Mr. Macmillan pointed out that the supply of United Kingdom reactors, which were fully developed and available on ordinary commercial terms, was governed by very different circumstances from those which led to the United States–Euratom agreement. The latter agreement provides the framework for the joint construction of prototype reactors of American design which are still in the development stage. Under it, the United States will assist Euratom in a ten-year programme of reactor research and development for which 100 million dollars will be provided in the first five years to build five or six nuclear power stations for commissioning in 1963. These stations, which are likely to be of the pressurized-water reactor type, will have a total generating capacity of about 5 million kilowatts, and for the construction, estimated at 350 million dollars, about 135 million dollars will be provided as long-term United States credits to Euratom. The United States will also provide enriched uranium for these plants at prices regarded by the West as 'give-away' prices, and the United States Atomic Energy Commission will guarantee for twenty years the endurance of the fuel elements under the agreement.

The contribution to the fuel economy of the six Euratom countries will not be important for its own sake, but the construction and operation of the reactors will allow the establishment of a cadre of nuclear technologists essential for larger developments. The agreement may also assist in the development of nuclear technology in the United States by expanding the opportunities for prototype trials; but there is nothing in this to be interpreted as a blow to British prestige or to offset the very definite advantages which Britain possesses. It would be wrong, as Sir Claude Gibb has emphasized, to over-stress the opportunities which export trade in nuclear power offers to Britain. In his view, the main assets which Britain has to offer to highly industrialized countries are her experience in design detail, in construction and in operation, and these hold potentialities for the reduction of initial capital costs which the Euratom countries are unlikely to overlook.

Friendly contacts have already been established in London with Euratom representatives, and the very great possibilities of the reactor chosen by Britain will certainly be recognized. It can be built, for example, by quite modest extension of conventional engineering techniques, and offers good prospects of decreased capital costs. The use of natural uranium is a further advantage, for in view of the distribution of uranium, most countries employing this type of reactor could look forward to becoming self-supporting in fuel supplies.

Power stations of this design thus can, and probably will, be sold in Europe while the American construction programme gets under way; and there is no reason for being pessimistic about the future of developments in Europe because of the Euratom agreement with the United States, provided due regard is had, first to our relations with Euratom, and secondly, but no less important, to the magnitude of the British nuclear power programme in relation to the other demands on our limited resources. Mr. Macmillan's statement indicates the Government now realizes the importance of establishing our relations with Euratom on a proper footing, and that something more than a research link is needed; but whether the Government appreciates the significance of the second point is still rather doubtful.

The reply to a question in the House of Commons on July 1 disclosed that the survey of expenditure on research and development made in 1955 is still being examined, and no plans have yet been made for a further survey. Yet, to take one point alone, the demand on Britain's scientific and technical man-power, as well as on material resources, should have been one factor to be considered in determining how best to meet our need for plutonium, if not the magnitude of those needs. Sir Claude Gibb recently estimated that the British nuclear industry is already employing 10,000 engineers and scientists on research and development, and said that the effort to prepare tenders for one of the first 300-MW. nuclear power stations in Britain approaches 1,000 man-years—the figure which Sir Edwin Plowden has given for initial research and development after the completion of basic research study of feasibility. Considering his further estimates that, for one year's study of feasibility and an experimental reactor, fifteen to a hundred scientists or engineers may be required, 100–150 engineers for a year's work on reactor design, a staff of 200 for a two-year study of the reactor and 100 for the three years to build a prototype reactor and control experiments with the reactor, and that, including the necessary support facilities, each professional scientist or engineer employed costs the Atomic Energy Authority about £10,000, the magnitude of the effort required from the limited scientific and engineering man-power of Britain becomes apparent.

This effort by the Atomic Energy Authority—and its further part in training technologists—has to be added to the 10,000 employed already in nuclear work by industry, and to the effort in nuclear research which the universities are also making, and to which the Department of Industrial and Scientific Research makes significant grants. Doubts may well be felt as to how far Britain is able to support an export programme in nuclear power; but there can be none as to urgency of the task of expanding our resources in scientific, technological and technical man-power. The over-riding message of the White Paper on capital investment in the coal, gas and electrical industries, however, is the vital and urgent need for as accurate assessment as possible not simply of the demands which nuclear power is making on capital and other material resources but of its demands on the scientific and technical man-power of Britain and its relation to the magnitude and distribution of our effort in research and development generally. Only when the magnitude of nuclear power development is seen in proportion to the national effort and resources generally can it be judged whether the balance is sound and how far further development is prudent.

NEW IDEAS ABOUT MUSCLES

Bioenergetics

By Albert Szent-Györgyi. Pp. x+143. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1957.) 4.50 dollars.

"THERE is but one safe way to avoid mistakes—to do nothing—or at least to avoid doing something new. This, however, may be the greatest mistake of all." With these characteristic words Szent-Györgyi prefaces his book on bioenergetics. If his scientific readers expect to get from his book a precise report on ascertained facts they will be disappointed. Szent-Györgyi's work has throughout been marked by its bold advances, by its intuitions which, seeming rash at the time, are afterwards found to be verified.

In the field of muscle physiology, which still remains his chief centre of interest, if anyone so exuberant can be limited to one centre, his speculations and experiments of twenty years ago on actin and myosin were first of all regarded as fantasies but have now become the cornerstone of muscle biochemistry. Anyone who disregards Szent-Györgyi's intuitions takes a very big risk—they may turn out to be true. In this book he is speculating about one of the aspects of living structure which has usually fallen by the way, but which is essentially the main one of all. The problem is, in his own words, "How does energy drive life?"; "How does it move the living machine?" It is this problem, first in relation to muscle contraction and later on in the book related to many aspects of living performances, that Szent-Györgyi has his new suggestions to make. It is essentially an attempt to weld together ideas on physiological actions, on quantum relations, particularly with regard to excited states, especially the triplet state, and to examine the action of the chief magician of biological systems, adenosine triphosphate and its so-called energy-rich phosphate bond. It is true that the richness of the bond has been somewhat deflated in recent years, but it still remains a most remarkable fact that nearly all the energy changes that have been carefully studied in living systems operate through the making or breaking of such bonds and it is usually in connexion with adenosine triphosphate or very similar substances. It was Szent-Györgyi himself, refining the work of Needham and Engelhardt, who showed that the contraction of muscle is, as he says, "essentially the interaction of acteomyosin with ATP and ion". Most other biochemists would say it is associated with, or connected with this interaction, but Szent-Györgyi scorns any such qualifications.

He produces in his first chapter a picture of muscle contraction based on the rearrangement, inside an elongated myosin molecule, of the far smaller globular proteo-myosin molecules of molecular weight 4,500. Such reorganization has, however, still to be demonstrated. It seems more and more unlikely in view of the detailed picture presented by the electron microscope in the hands of Huxley and others. Indeed, any mechanism of muscle contraction involving the chain-length of a particular filament is probably inadequate. However, this does not effect Szent-Györgyi's subsequent argument, which is mostly concerned with how the energy needed for contraction gets into the muscle filament. Essentially, Szent-Györgyi's hypothesis can be written in his terms in the formula:

$$\xleftarrow{\qquad} \text{muscle activity, luminescence}$$
$$E_n \ldots \rightleftarrows E_3 \rightleftarrows E_2 \rightleftarrows E_1 \rightleftarrows E^* \rightleftarrows h\nu \text{ or } w$$
$$\xrightarrow{\qquad} \text{photosynthesis}$$

where E_n represents the energy reserve of the system and $h\nu$ or w, as the case may be, the light or mechanical work absorbed or given out. The characteristic feature on which he lays stress is the term marked E^* interposed between the last energy state and the final quantum product. This is the excited molecular stage. Szent-Györgyi here postulates the need for a special molecular configuration to allow this energy to travel from one part of the molecule to the other. These considerations lead him into a study of the photo-emission and photo-absorption of molecular systems, with the phenomena of fluorescence, phosphorescence and quenching. The intermediate states of the electronic excitation system can pass, exceptionally, through triplet forms, and these triplet forms of excitation he treats rather in the same way as the free radicals. As in the case of free radicals he imagines them to be immobilized in suitable states, particularly the glassy state. He equates the energy of the energy-rich phosphate bond, taken as 10 kcal., as corresponding to a wave-length of 2–3μ in the near infra-red. Modern measurements give it as nearer 6 kcal. and therefore in the range of 5–6μ, even farther in the infra-red. However, he does not expect these bonds to be stimulated directly by visible light, which has a far higher energy, but only through some intermediate mechanism.

So far Szent-Györgyi has followed fairly straightforward quantum chemical lines. He breaks new ground, however, by associating the conditions of triplet excitations and energy-transfer with the properties of water or, more particularly, of ice. He describes a series of beautiful qualitative experiments by which the fluorescence of certain dyes and certain biologically active substances has profoundly altered the freezing of the water in which they are dissolved. Ordinary freezing is less effective than sudden deep freezing in 'dry ice'. As, however, he carefully states that these effects are spoilt by substances such as glycerol, which prevent ice crystallizing, it is difficult to see that he is doing anything other than studying the reactions of such molecules expelled from the solution on the formation of ice crystals. It may be, however, that they are actually incorporated in the ice-crystal structure, but this would require more proof than he provides.

As he says himself, "when considering water structures we enter fantastic and fascinating worlds". It is certain that the experiments described here deserve to be taken up again under controlled conditions to find out what produces the large effects that he has observed. In any event, they are worth while in directing attention to the states of aggregation of water in biological systems, especially at low temperatures, of which the remarkable work of Dr. B. J. Luyet has shown the degree of complexity. Szent-Györgyi himself now tends to turn to water to explain a number of phenomena where previously attention had been devoted to the more purely biological structures such as myosin, particularly the role of bound water on the surface of protein and other intracellular micelles.

Szent-Györgyi heads the second part of his work on biological structures and functions with the remark, "Research is to see what everybody has seen and to think what nobody has thought". Earlier he says: "The more we learn about myosin the less we understand it, which suggests we are looking at it in the wrong way". In this section he turns to the structure of the water outside the muscle, which after all makes up more than 80 per cent of its weight, to set the picture to rights. He uses this concept not so much to explain the contraction of muscle but, in his characteristically upside down way, to explain the relaxation of muscle. As he says, "the problem of contraction is not what makes the particle shorten but what keeps them extended when at rest, or stretches them out again after contraction". This he explains by a kind of crystallization of the water in the immediate contact with myosin particles.

There follows a discursive but most suggestive account which links this with the action of adenosine triphosphate in other systems, and much complex biochemistry concerned with the various types of interference with energy transfers, for example, that produced by 2 : 4 dinitronaphthol or by iodine. There is no space here to go into the whole of the numerous fascinating suggestions he makes covering the whole range of biochemical and physiological phenomena. For example, he discusses the action of the drug chlorpromazine in the treatment of schizophrenia, provides an explanation of myotonia in relation to the action of the drug 2 : 4 dichlorphenoxy acetic acid which artificially produces the same symptoms, and in general discusses the whole question of health and disease right down to "oxidation, fermentation and cancer" in the last chapter.

On almost every page there is some idea worth thinking about and worth starting some new experiments to prove or disprove. It is a book which will inspire many and infuriate some. To quote Belloc's preface to "Ruthless Rhymes", "And is this true ? It is not true; And if it was, it would not do". Or rather, it does not matter. In the present revolutionary state of biochemistry, such challenging ideas may be more important than carefully checked measurements of unimportant phenomena.

J. D. Bernal

A HUNDRED YEARS OF CHEMICAL INDUSTRY

The Chemical Industry during the Nineteenth Century

A Study of the Economic Aspect of Applied Chemistry in Europe and North America. By Dr. L. F. Haber. Pp. x+292. (Oxford: Clarendon Press; London: Oxford University Press, 1958.) 45*s.* net.

THERE is no more rewarding background study for a young man entering the chemical industry than the history of its development during the past hundred years or so. The research chemist will learn much from the successes and failures of his predecessors. Almost unconsciously he will acquire a sense of scale and a perception of values which will help him to relate the worth of his individual work to the future prosperity and expansion of the industry in which he is engaged. The young plant manager will derive encouragement from the accounts of the start of new processes and of operating difficulties successfully overcome by resourceful engineering. A study of the rise and fall of varying methods of manufacture due to different raw materials, different chemical efficiencies and the changing requirements of customers cannot fail to stimulate interest in the economic prosperity of the process he is operating or developing.

The publication of Dr. L. F. Haber's book, "The Chemical Industry during the Nineteenth Century" is therefore to be warmly welcomed.

The book is a mine of detailed information and the accuracy is of a high order. Particularly valuable for the student are the ample footnotes with their references to the original sources. The compilation of the book must have involved the author in an immense amount of devoted labour.

It is not, however, very easy reading, partly on account of the number of detailed facts, some of which, though interesting in themselves, are to a certain extent irrelevant to the main themes of the book, but also because of the rather curious division of the chapters. Some of them deal with special topics, such as "New Schools of Science", "New Technologies" and "The Workers in the Nineteenth Century Chemical Industry", over the whole of the period under review, whereas others deal with the history of such processes as Leblanc soda manufacture and the ammonia–soda process in sections divided into arbitrary periods of time which have no special relation to technical changes or commercial competition. The author, in his introduction, rightly emphasizes the great interest of the changing role of the Leblanc soda trade, but in the book the story is cut into half a dozen sections unrelated except by a certain degree of repetition.

It would be of great interest to the student if the author, at some future date, could write the fascinating story of the development of the alkali industry as a thesis in itself. The main facts and factors involved are already in the present book, but their presentation as a continuous story would bring out far more clearly the reasons for the decline and fall of the Leblanc process and the technical and economic changes behind it.

The chemical industry exists primarily to serve the raw material requirements of other industries. As the standard of living increases, so does the extent and prosperity of consumer industries grow. The chemical industry grows with them.

In the nineteenth century, the remarkable increase in the textile industry in the United Kingdom, and to a lesser extent in the production of glass, paper and soap, brought with it a rapidly increasing demand for soda ash, for bleach, for sulphuric acid and for saltcake. It is difficult to realize to-day that in the decade 1870–80 the demand for bleaching powder, owing to the enormous size of the cotton textile industry, was nearly as big as the demand for soda ash. It was for this reason that, in spite of the chemical elegance of the ammonia–soda process and the great technical advantage of a continuous process as opposed to the batch working of the Leblanc manufacturers, Brunner Mond and Co. were forced to make chlorine and bleaching powder from the liquor of the ammonia–soda process. The daring and technically successful achievement of Dr. Mond in producing chlorine from ammonium chloride (incorrectly described as "calcium chloride" on p. 159) by vaporizing it and passing it over nickel oxide pills was costly, but it served its commercial purpose by preventing the Leblanc manufacturers from increasing the price of bleach and selling soda ash as a by-product at give-away prices. The interesting graph of bleaching powder prices in Appendix 5 illustrates this well.

The sections of the book dealing with the development of the dyestuffs industry make interesting reading, though here again the story suffers from a certain lack of continuity which makes it difficult to follow the economic factors involved.

The chapter entitled "Chemical Manufacturers and their Problems" gives a number of tables illustrating movements in international trade in chemicals and directs special attention to the effect of tariff changes. A particularly vivid example which is quoted is that of the Dingley tariff in the United States. Until the early 'nineties, the United States was by far the most important export market for British alkali manufacturers, taking the enormous quantity of more than 150,000 mixed tons. Within a year or two of the imposition of the tariff, British exports had diminished to a mere trickle.

J. L. S. STEEL

THE STATISTICAL DESCRIPTION OF VEGETATION

Quantitative Plant Ecology

By P. Greig-Smith. Pp. ix+198. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1957.) 30*s.*; 6 dollars.

THIS book deals primarily with some of the statistical approaches to the problems of describing the distribution of vegetation and, in a few cases, of species. The basis of these techniques involves concepts such as those of density, frequency and cover, which are first explained and then used to introduce the principles involved in sampling, the arrangement and size of the units of estimation and the comparison of the results of different sets of observations. A considerable part of the book is devoted to the analysis of what is called 'pattern' in vegetation—defined as the departure from randomness of distribution of individuals within the plant community—and then to the possible relationships between the patterns shown by different species and their correlation or lack of correlation in distribution. Finally, consideration is given to the possibility of delimiting plant communities on purely objective grounds and the bearing of this upon the classification of vegetation.

Although one chapter gives examples of correlations between vegetation and the level of environmental factors, the book is not primarily concerned with ecology in the usual sense of the word—the relation between organisms and their environment—or with the quantitative study of these relations as estimated, for example, by weighing, counting or measuring. To this extent the title is a misnomer. It is, indeed, in the reviewer's estimation the only part of the book open to real criticism.

Although ecologists dealing with vegetation have usually accepted the simplest descriptive units which could be clearly defined (hence often a species) as the quantitative basis for correlations between vegetation and environment, most of them at some time have also wished for larger units with objective biological significance. Long ago this was the initial attraction of the methods of the Upsala school, though in that case, as so often since, the hope was soon dispelled. This ideal the author of this work keeps clearly in mind and the great merit of the book is that it discusses at frequent intervals the basic problems which have to be faced in arriving at suitable underlying concepts. It indicates how, in the author's opinion, solutions might be found. While the reader may find himself at times unable to agree with the author, he will certainly also find the discussions thoughtful and stimulating, though, as is often the case in such matters, it is not possible to convey their interest in a short review.

This is a useful and timely book: useful, because it collects most of the pertinent arguments and statistical methods in one volume; timely, because it tries to integrate the large recent accessions of literature in this field and also because it presents and unifies ideas and thus will undoubtedly form a basis for further advances. W. H. Pearsall

SCIENCE FOR STUDENTS OF THE HUMANITIES

Harvard Case Histories in Experimental Science

Edited by James Bryant Conant and Leonard K. Nash. Vol. 1. Pp. xvi+322. Vol. 2. Pp. v+323–639. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1957.) 80*s*. net the set.

The case histories in experimental science introduced to Harvard by J. B. Conant have become widely known as representing an interesting experiment in the teaching of science to non-scientists. The collection of eight of these case histories into two volumes, under Conant's editorship, has now made them easily available to English readers. The 'cases' are concerned with: Boyle's experiments in pneumatics; the overthrow of the phlogiston theory; the early development of the concepts of temperature and heat; the atomic–molecular theory; plants and the atmosphere; Pasteur's study of fermentation; Pasteur's and Tyndall's study of spontaneous generation; the development of the concept of electric charge.

Each 'case' is in the form of a self-contained essay aimed at bringing the reader into the frame of mind of the earlier experimenters and at showing him how difficult it often was for investigators to make a break with tradition and to start thinking along new lines. It is shown how the change in point of view depended jointly on experimentation and on imaginative conjecture, and how the approach was seldom direct, but when seen from our more enlightened point of view seems often to have been roundabout and tortuous. To bring the reader more closely into contact with the mental attitude of the original investigators, skilful use is made of quotations from original papers.

It is difficult for a scientist to assess how far a non-scientist would find these essays interesting or instructive. For that it is best to rely on experience in the United States, where, at Harvard and elsewhere, they have been highly successful, in the hands of skilled teachers, in transmitting something of the principles of scientific investigation to those whose main studies were in the humanities.

To a scientist, however, there is no doubt at all that the essays provide an excellent account of how a series of discoveries came about, and the reader finds himself sharing in the excitement of the early investigators. Most scientists will find much that is new, even in the history of their own subject. I learnt for the first time, for example, how Hauksbee's experiments led him by curiously devious routes from the study of the flash of light which sometimes occurs in the space above the mercury when a barometer tube is shaken, to the discovery of several new phenomena in electrostatics and, in particular, to that of electrostatic induction.

Most degree courses in science are so concerned with imparting the maximum of 'useful' knowledge that neither teachers nor learners often find time to inquire just how some of the concepts they take for granted really arose. It is difficult to avoid being swept along with this rushing stream of education and discovery; but if it is to be education in the true sense, and not just the acquiring of technical knowledge which will 'work' when one has to solve a problem, it is necessary to pause at intervals and ask how some of our present-day scientific concepts first arose.

These volumes will provide quiet backwaters into which the research worker or teacher can turn and linger for a short time to study what has happened to the streams of discovery before he joined it, and before he joins it again in his headlong rush to make those advances in knowledge which will form the subject of 'case histories' in the future.

J. A. Ratcliffe

THEORETICAL OPTICS

Geometrical and Physical Optics

By Dr. R. S. Longhurst. Pp. xvi+534. (London and New York: Longmans, Green and Co., Ltd., 1957.) 60*s*. net.

Without necessarily asking too much from the reader of limited mathematical attainment, Dr. Longhurst has given a most comprehensive account of geometrical and physical optics at degree standard which should be widely welcomed. For the pass or general degree student, the treatment is taken as far as possible along elementary lines. The more difficult mathematical work is grouped into separate sections, for those who have to read more deeply; and modern experimental work, and practical applications of optical techniques, are discussed at a level which should prove both helpful and stimulating to the more advanced student who may later specialize in optics.

The first five chapters deal with the general geometrical theory of the perfect image-forming optical system, the paraxial theory of optical instruments, the determination of the constants of optical systems, and the use of the prism in refractometry and spectroscopy. Next, the mathematical treatment of the wave equation, and the ideas of coherence and wave and group velocity, introduce the wave theory of light. Three chapters on interference follow—treating the interference of two beams by wave-front division, that of two beams by amplitude division, and multiple-beam interferometry. Chapter 10, after a critical discussion of Fresnel's theory of diffraction, deals fully with Kirchhoff's diffraction formula, and then explains the basis on which diffraction patterns are classified as 'Fresnel' or 'Fraunhofer'. Chapter 11, on the single slit, and Chapter 12, on diffraction gratings, between them cover all aspects of Fraunhofer diffraction. Chapter 13 deals separately with the Fresnel type. It is usual (and indeed essential if they are to be intelligible) to dissect interference and diffraction effects in this manner, but it is rarely so constructively done; and it is a great assistance to find practical applications such as the Twyman-Green interferometer, the wave-front shearer, and the Sears-Barrell length-standard work, classified likewise under the appropriate heading.

Chapters 15 and 16 discuss the aberrations of lenses, the means of controlling them in optical systems, and a number of standard lens combinations. The chapter on visual optics deals also with colour; that on photometry is chiefly concerned with standards and with visual photometry. The final chapters deal with the electromagnetic theory, the propagation of light in crystals, optical activity, and the velocity of light. Much has been done since R. T. Birge's review of this last subject in 1941, and a good account of the work up to 1957 is given here.

This last comment summarizes one quite striking feature of the book; that it is the work of an enthusiast who would have his students well informed on current progress. But the whole is unusually well planned for its purpose, from the patient sorting out of the sign convention at the beginning to the arrangement of the severer mathematics for "omission at a first reading"; it is a really excellent book. Dr. Longhurst, in the preface, calls it "a student's textbook". This it most certainly is, but there must be many people well past their student days who will find it to be a valuable work of reference.

G. R. Noakes

HISTORY OF IRON IN BRITAIN

History of the British Iron and Steel Industry from c. 450 B.C. to A.D. 1775

By Dr. H. R. Schubert. Pp. xxi+445+26 plates. (London: Routledge and Kegan Paul, Ltd., 1957.) 60*s*. net.

TOWARDS the end of the fifteenth century a technological discovery was made which revolutionized the iron industry and was, in fact, the harbinger of our modern civilization. From the very beginning of the Iron Age this metal had been produced by the direct reduction of the ores in furnaces of small size in which the temperature normally never attained that required for fusion, though it is certain that on occasion and by accident the sponge iron produced became carburized to such an extent that a molten product—white cast iron—was obtained. As the size, and particularly the height, of the furnace in which the reduction was effected was increased, higher and higher temperatures were attained until, finally, the forerunner of the modern blast-furnace was developed and molten iron was produced deliberately. This great change in technique resulted in a relatively enormous increase in output. It further provides the justification for the division of this really important contribution to the history of technology into two parts, the first concerned with the early history of a process which resulted in a soft sponge iron, the latter in the production of molten cast iron, used at first mainly for the production of military castings, which required a second process for its conversion into a malleable product.

The author, a professional historian, surveys the whole history of the industry from the first introduction of iron to Britain to the time when molten steel was produced commercially by the Huntsman process; but nowhere is his background shown to better advantage than in the skill with which he has revealed the extent to which the introduction of the blast-furnace increased the output of metal obtained. In the course of a few decades the daily output per furnace was raised some seven times. The wide field over which the material has been collected and the great skill with which it has been sifted and woven into a surprisingly coherent story deserve the highest praise.

Of the earliest English blast-furnaces neither picture, description nor remains have been preserved: the furnace, previously supposed to be of this nature, from a drawing in the Public Record Office, was, in fact, a lead furnace erected in Derbyshire about 1552. It is, therefore, from the accounts of the Sussex ironworks, from 1541 onwards, that it has been possible to obtain some idea of the structure as it existed in the early sixteenth century, and the author has been able to reconstruct the main outlines of this piece of equipment, a description which is rendered the more vivid from the excellent coloured frontispiece of a painting by the Flemish artist, Blès.

There are certain minor imperfections in the text: W. Goland of Appendix 1, for example, should surely be Prof. W. Gowland, and that the author is not himself a metallurgist is here and there apparent. It is this fact, presumably, which leads him to perpetuate the heresy that there was some special virtue or magic in ores containing small amounts of manganese and titanium which rendered it possible for primitive metallurgists to produce a steel, as distinct from soft iron, in the early direct furnace. It is quite easy to do this even in the complete absence of either of those elements by allowing the reduced sponge to remain in contact for a sufficient time with the glowing charcoal.

Despite such blemishes, however, there can be no question that the volume under consideration is one of quite outstanding merit, for which the archæologist and technologist alike owe a very deep debt to the author himself and to the Iron and Steel Institute, through the support of which the researches here recorded were carried out.

F. C. Thompson

Nuclear Engineering

Edited by Prof. Charles F. Bonilla. (McGraw-Hill Series in Nuclear Engineering.) Pp. xi+85 (London: McGraw-Hill Publishing Company Ltd., 1957.) 94*s*.

TWELVE specialists have collaborated in writing this book. Of the 800 pages, 170 are devoted to nuclear physics and associated subjects, 100 to reactor physics and shielding theory, about 300 to thermal and structural considerations, about 60 to instrumentation and less than 20 to metallurgy.

Although the nuclear physics is well presented, a more rigorous selection of topics with greater emphasis on those of immediate importance would have pleased the reviewer. There is a well-written chapter on radiation protection, which includes a clear explanation of the units used, the variety of which usually bewilders students.

Reactor physics is not allotted enough space and too much is attempted in the space available. In covering neutron cycles, flux, extrapolation distance, one group, multigroup and age theories, and resonance absorption effects, as well as discussing transport and diffusion theories and other topics in the space of 30 pages it has only been possible to survey the subject.

The real value of the book lies in its treatment of thermal and structural aspects of reactors, and for this section it can be recommended. There is a stimulating discussion of the potentialities and problems of non-elastic design methods.

Concluding chapters deal with reactor types and legal aspects of nuclear power.

As a text-book it suffers from having too many authors; as a work of reference its value is enhanced by the many references included, particularly on heat transfer, but weakened by an inadequate index.

W. Murgatroyd

A Revision of the Australian Chafers (Coleoptera: Scarabaeidae: Melolonthinae)

By E. B. Britton. Vol. 1. Pp. viii+186+42 plates. (London: British Museum (Natural History), 1957.) 80*s*.

IT is now generally recognized that an effective investigation into the biology and control of any group of animals must be based upon a sound taxonomy, but all too frequently this basic requirement remains unfulfilled until a very late stage, when already much effort has been wasted because of faulty identification. In the present volume the systematics of an important group of beetles is placed upon a satisfactory footing in a comparatively early stage of the investigation. The damage done by the Melolonthinae as a whole is of considerable economic importance, and it is chiefly due to the root-feeding habits of the larvæ. A great variety of plants are attacked by one or other of the species: grasses and various field crops including maize and sugar cane and also vegetables and fruit. Sometimes a considerable amount of damage is done by the adults of some species that feed upon the leaves of shade and fruit trees and also injure vines. It is somewhat surprising to find that all the pest species are indigenous, as indeed are all other Melolonithinae of Australia.

The volume is exceptionally well illustrated; there are 524 figures of which all but 25 drawings of the whole insect are arranged in 42 plates at the end. Most of the figures are simple but good outline drawings of the male genitalia and of the head and prothorax of the different species. The keys are well done in the best modern style, and there would seem to be no difficulty in choosing between the alternatives offered in each couplet. Thirteen tribes are recognized of which no less than ten are described as new. The Sericini and four of the new tribes are dealt with in this first volume. These five tribes include 203 species of which 67 are described for the first time.

H. E. Hinton

Fibre Microscopy

Its Technique and Application. By Dr. J. L. Stoves. Pp. viii+276. (London: National Trade Press, Ltd., 1957.) 50*s*. net.

SO much is the make-up of all biological tissues of a fibrous construction, so much does man put numerous animal and vegetable fibres to supplementary uses, and so much has he now extended the idea into similar fields more purely of his own invention, that there is a continual need for good and up-to-date writing on the subject, and a new book of the kind on fibre microscopy can scarcely fail to be most acceptable to all sorts of readers. Dr. Stoves, out of his wide experience and contacts in such matters, has certainly provided one in the volume noticed here, directed to "students, laboratory assistants, analysts and research workers"—and that means, among many others, archæologists and criminologists, for example; and he has spread its informative coverage over all the latest developments, including, of course, phase-contrast, interference and reflexion microscopy and, of ever-growing importance these days in spite of the expense, electron microscopy (plus, it should be mentioned, a chapter on metal shadow-casting in visible microscopy). He applies them then to the examination of almost anybody's fibres, so to speak. There are also excellent bibliographies and suggestions for further reading, indexes of animals and plants, and lists of stains and staining reactions. Altogether, this is a very worthwhile book indeed.

W. T. Astbury

Bakteriophagie 1917 bis 1956

Zugleich ein Vorschlag zur Dokumentation wissenschaftlicher Literatur. Von Dr. Hansjürgen Raettig. Teil 1: Einführung—Sachregister—Stichwortverzeichnis. Pp. xix+215. Teil 2: Autorenregister. Pp. iii+344. (Stuttgart: Gustav Fischer Verlag, 1958.) 44 D.M.

THESE two little books are intended as a guide to the literature on bacteriophage published between 1917 and 1951; they are a monument to German industry and thoroughness. Vol. 2 lists under authors no less than 5,655 references. Looking up fifty references, some of them from rather obscure journals, failed to reveal one which was not listed, and quite a large number from Russian journals are included. Vol. 1 classifies the material under subjects; here the arrangement is good but not perfect. A few omissions were detected: for example, *Escherichia* is unaccountably missing on p. 137. The books suffer, as do most bibliographies, from the defect that one cannot tell which of the many references are the really important ones.

The format is excellent; the limp covers in an attractive blue-grey add to the appeal of the volumes. Anyone who has to write an article, a review or even a book on phage will find that Dr. Hansjürgen has saved him much of his labour.

EDITED PROCEEDINGS OF THE

SECOND INTERNATIONAL CONFERENCE ON THE PEACEFUL USES OF ATOMIC ENERGY, GENEVA

SEPTEMBER 1958

PERGAMON PRESS is pleased to announce that the Board of Editors of Progress in Nuclear Energy, the International Review Series in Atomic Energy, have made arrangements to publish the Edited Proceedings of the Second International Conference on the Peaceful Uses of Atomic Energy in twelve separate volumes, similar to those edited by them and published by Pergamon Press on the First International Conference on the Peaceful Uses of Atomic Energy held in Geneva in 1955.

All volumes will be published and distributed between December 1958 *and April* 1959. *In order to ensure receipt of copies immediately upon publication, please place your order now.*

Customers who have already a standing order for the Progress in Nuclear Energy Series will automatically receive the appropriate volumes.

Pre-publication Price valid until October 1st, 1958

Single Volumes 90s. ($12.50)
Complete set of 12 volumes £50 ($140)

Price after October 1st, 1958. Single volumes £5 5s. ($15). Complete set of 12 volumes £63 ($180)

Title of Volume	*Series No.*	*Editors and Location*
Physics and Mathematics	I	D. J. Hughes, *Brookhaven*; J. E. Sanders, *Harwell*; J. Horowitz, *Saclay*.
Reactors	II	N. L. Franklin, *Risley*; B. I. Spinrad, *Argonne*.
Process Chemistry	III	F. R. Bruce, *Oak Ridge*; J. M. Fletcher, *Harwell*; H. H. Hyman, *Argonne*.
Technology and Engineering	IV	R. Hurst, *Dounreay*; R. N. Lyon, *Oak Ridge*.
Metallurgy and Fuels	V	H. M. Finniston, *Harwell*; J. P. Howe, *Canoga Park, California*;
Biological Sciences	VI	J. Bugher, *Rockefeller Foundation*; J. Coursaget, *Saclay*; J. F. Loutit, *MRC Harwell.*
Medical Sciences	VII	J. Bugher, *Rockefeller Foundation*; J. Coursaget, *Saclay*; J. F. Loutit, *MRC Harwell.*
Economics of Nuclear Power	VIII	J. A. Lane, *Oak Ridge*; Philip Sporn, *New York*; P. W. Mummery, *Harwell*; I. R. Maxwell, *London.*
Analytical Chemistry	IX	Editors being appointed.
Law and Administration	X	Herbert S. Marks, *Washington D.C.*
Plasma Physics and Thermo-Nuclear Research	XI	J. L. Tuck, *Los Alamos*; C. Longmire, *Los Alamos*; W. B. Thompson, *Harwell.*
Health Physics	XII	Karl Z. Morgan, *Oak Ridge*; W. G. Marley, *Harwell.*

Some of the Topics to be covered in these Edited Proceedings:

The Future of Nuclear Power. Experience with Nuclear Power Plants. The Use of Nuclear Energy for purposes other than the generation of electricity (for example, Marine Propulsion). The possibility of developing thermo-nuclear Power (by fusion instead of fission). Progress in the use of Radioactive Isotopes. Operational aspects in Health and Safety. Aspects in Nuclear Power Programmes. Recent Developments in Fundamental Physics. Reactor Technology and Chemistry. Properties of Reactor Materials. Treatment and handling of Radioactive Wastes. Processing of Irradiated Fuel Elements. Problems in Nuclear Fusion. Fuel Cycles and Economics of Nuclear Power. Use of Research and Test Reactors and Reactor Experiments. Dosimetry and Standards. New Uses of Isotopes in Medicine. Use of Isotopes in Biochemistry and Physiology. Use of Isotopes in Research, Control and Industrial Technology. Use of Isotopes in Agriculture. Experience in Radiological Protection. Biological Effects of Radiation. Fabrication of Fuel Elements including the Metallurgy of Uranium, Thorium, Plutonium and their Alloys

An 8-page brochure, describing in full detail the Edited Proceedings, is supplied free on request. Please write to:

SEPARATION OF LIGHT AND DARK PHASES IN THE PHOTOSYNTHESIS OF ISOLATED CHLOROPLASTS

By Dr. ACHIM V. TREBST, HARRY Y. TSUJIMOTO and Prof. DANIEL I. ARNON
Laboratory of Plant Physiology, Department of Soils and Plant Nutrition, University of California, Berkeley

THE recognition of a 'dark', that is, a thermochemical phase in photosynthesis, had its origin in Blackman's findings[1], that at high, but not at low, light intensities the rate of photosynthesis is dependent on temperature. Warburg named this thermochemical stage of photosynthesis the Blackman reaction and established its sensitivity to cyanide[2]. The present communication reports the physical separation, by fractionating chloroplasts, of the light and dark phases of photosynthesis. The light phase was completed first and was then followed by the dark phase. The two phases, when carried out consecutively, yielded essentially the same final photosynthetic products as the continuously illuminated complete chloroplast system.

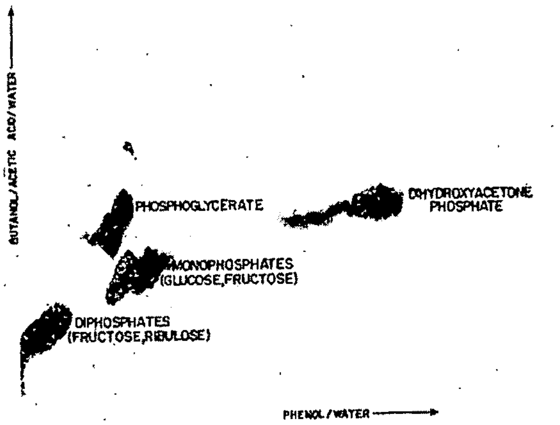

Fig. 1. Radioautograph of a chromatogram showing products of photosynthetic $^{14}CO_2$ assimilation by illuminated chloroplasts. Experimental conditions as in treatment 3 of Table 1

It has recently been shown that the organization of the living cell is not necessary for photosynthesis as it is usually defined[3]. Reduction of carbon dioxide to carbohydrates accompanied by oxidation of water to oxygen is carried out, at low temperatures and with no energy supply except visible light, by isolated chloroplasts, unaided by other cellular particles or enzyme systems[4-12,13-15].

This extracellular photosynthesis by chloroplasts differs from that process in whole cells notably in that it proceeds independently of concurrent cellular activities, such as respiration, which cannot be divorced from photosynthesis in intact cells[16]. Isolated chloroplasts, if freed from other cytoplasmic impurities, do not respire[6,10,17]—a conclusion which has recently received strong support from the work of James and Das[18]. The products of photosynthesis by isolated chloroplasts are mainly carbohydrates; amino-acids were not formed in the experiments reported here (Figs. 1, 2, 3). The role of amino-acids in photosynthesis has assumed special interest in the light of Warburg's[19] recent findings with *Chlorella* cells.

Although extracellular photosynthesis by chloroplasts cannot be equated in all respects with photosynthesis in intact cells it retains the principal features of that process, and permits their investigation in isolation from concurrent cellular activities. The separation of photosynthesis by chloroplasts from the structural and functional complexity of the

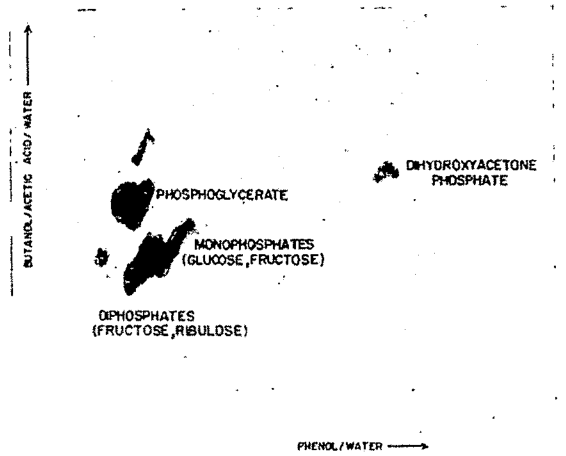

Fig. 3. Radioautograph of a chromatogram showing products of dark $^{14}CO_2$ assimilation by a chlorophyll-free extract of chloroplasts supplemented with adenosine triphosphate, and reduced triphosphopyridine nucleotide formed by the oxidation of isocitrate. Experimental conditions as in treatment 9 of Table 3

whole cell has provided a particularly useful approach to the study of those problems in photosynthesis in which a clear distinction from the dark reactions of respiration is especially pertinent. One of these problems is the relation between the light and dark reactions in photosynthesis.

The Photochemical Phase of Photosynthesis : Oxygen Evolution and the Generation of Assimilatory Power

Systematic studies of the photochemical reactions of isolated chloroplasts, without the participation of carbon dioxide, began with the experiments of Hill[20] in 1937. Recent progress which led to the characterization of the physiological products of these reactions came from two directions : the finding of a photochemical phosphorylation system in chloroplasts[21] and, as will be discussed next, the identification of the reductant for the assimilation of carbon dioxide.

Vishniac and Ochoa[22], Tolmach[23], and Arnon[24] found that, in light, isolated chloroplasts can reduce pyridine nucleotides and simultaneously evolve oxygen, if this photochemical reaction is coupled with an enzyme system capable of utilizing the reduced pyridine nucleotides. A direct reduction of pyridine nucleotides by illuminated chloroplasts, as measured by the accumulation of the reduced product, was demonstrated by San Pietro and Lang[25]. Evidence has also been obtained that triphosphopyridine nucleotide rather than diphosphopyridine nucleotide is preferentially reduced in light[26,27].

Another photochemical process occurring in isolated chloroplasts is photosynthetic phosphorylation, that is, the utilization of light energy for the synthesis of high-energy phosphate bonds in accord with the overall reaction 1, where P represents orthophosphate and ADP and ATP represent adenosine diphosphate and triphosphate, respectively.

$$n.\mathrm{ADP} + n.\mathrm{P} \xrightarrow[\text{chloroplasts}]{\text{light}} n.\mathrm{ATP} \qquad (1)$$

In reaction 1, all the captured light energy is converted into the high-energy pyrophosphate bonds of adenosine triphosphate. This type of photosynthetic phosphorylation has been named cyclic photophosphorylation[21].

The connexion between photosynthetic phosphorylation and the reduction of triphosphopyridine nucleotide was not clear at first, but was later, rather unexpectedly, found to be very direct[21,26,28]. It is shown in reaction 2.

$$2\mathrm{TPN} + 2\mathrm{ADP} + 2\mathrm{P} + 4\mathrm{H_2O} \xrightarrow[\text{chloroplasts}]{\text{light}} 2\mathrm{TPNH_2} + 2\mathrm{ATP} + \mathrm{O_2} + 2\mathrm{H_2O} \qquad (2)$$

In reaction 2, only part of the light energy absorbed by chlorophyll is trapped in the pyrophosphate bond of adenosine triphosphate ; the remainder is used for the formation of reduced triphosphopyridine nucleotide. Reaction 2 may therefore be viewed as representing the essential photosynthetic events in green plants : the transformation of light energy into chemical energy accompanied by the evolution of oxygen. The newly formed chemical energy is deposited in two substances, which have been jointly termed 'assimilatory power'[21] : a reductant (reduced triphosphopyridine nucleotide) and an energy-rich phosphorus compound (adenosine triphosphate).

The stoichiometry of reaction 2, when measured under appropriate experimental conditions[21,26,28], indicates that the formation of four hydrogen equivalents, needed for reduction of one mole of carbon dioxide to the level of carbohydrate (= CH.OH), is accompanied by the evolution of one mole of oxygen, as would be expected from the well-known photosynthetic ratio CO_2/O_2 of 1. In addition, two moles of adenosine triphosphate are formed. Whether these fulfil the requirements for adenosine triphosphate in the assimilation of carbon dioxide cannot as yet be stated with certainty[12]. If, however, reaction 2 cannot by itelf supply enough adenosine triphosphate for carbon assimilation then it could be supplemented, to a varying degree, by cyclic photophosphorylation (reaction 1).

To recapitulate, it is envisaged that in photosynthesis by isolated chloroplasts the photochemical events are the evolution of oxygen coupled with the generation of 'assimilatory power' (reaction 2), and cyclic photophosphorylation (reaction 1). It is assumed that the cell has suitable regulatory mechanisms for maintaining a balance between these two reactions[21]. What remains to be demonstrated is that the products of these photochemical reactions, reduced triphosphopyridine nucleotide and adenosine triphosphate, are used for the dark assimilation of carbon dioxide to the level of carbohydrates.

The Dark Phase of Photosynthesis : Carbon Dioxide Assimilation

Experiments to test the effectiveness of the products of photochemical reactions in carbon assimilation in the dark were undertaken as follows. Substrate amounts of 'assimilatory power' were first generated in light in the absence of carbon dioxide. At the end of the light reaction carbon-14 dioxide was supplied in the dark, and, after an incubation period, its total fixation was measured. The newly formed radioactive compounds were identified by paper chromatography and radioautography[7].

In carrying out the dark reaction it soon became apparent that the green portion of the chloroplasts was superfluous. In accord with previous results[8,9,11], the chloroplast enzymes responsible for carbon assimilation were present in the chlorophyll-free, water-soluble portion of the chloroplasts ('stroma'). The water-insoluble green portion of the chloroplasts ('grana') was therefore removed by centrifugation after the light reaction was completed. This separation by centrifugation was possible since the chloroplasts used were already disrupted through immersion in the hypotonic reaction mixture. $^{14}CO_2$ was then supplied to the chlorophyll-free extract which contained, in addition to the soluble enzymes, catalytic amounts of sugar phosphate[11] and the two components of assimilatory power generated in the previous light reaction : reduced triphosphopyridine nucleotide and adenosine triphosphate.

As shown in Table 1, in the presence of 'assimilatory power', the chlorophyll-free extract was able to fix $^{14}CO_2$ in the dark. Only feeble fixation occurred in the dark without the components of assimilatory power (treatments 1 and 2). The dark fixation of carbon dioxide by the chlorophyll-free extract supplemented with 'assimilatory power' was comparable with fixation in the light where $^{14}CO_2$ was supplied at the beginning of the illumination period to a reaction mixture containing the complete chloroplast system. Here 'assimilatory power' was formed continuously in the light and used at once for carbon dioxide fixation (treatment 3). Very little fixation

Table 1. CARBON DIOXIDE FIXATION BY A CHLOROPHYLL-FREE EXTRACT AND A COMPLETE CHLOROPLAST SYSTEM FROM SPINACH

Treatment	$^{14}CO_2$ fixed (counts/min.)
1. Chlorophyll-free extract, dark + A.P.*	134,000
2. Chlorophyll-free extract, dark − A.P.*	9,000
3. Complete chloroplast system, light	200,000
4. Complete chloroplast system, dark	20,000

* A.P. = Assimilatory power, that is, reduced triphosphopyridine nucleotide and adenosine triphosphate formed in light by chloroplasts.

The complete chloroplast system contained in a final volume of 2·5 ml. 'broken' chloroplasts (ref. 12) containing 0·5 mgm. chlorophyll, chlorophyll-free extract (ref. 12) equivalent to 2 mgm. of chlorophyll and the following in micromoles: *tris* (hydroxymethyl) aminomethane buffer, *p*H 7·5, 80; magnesium chloride, 5; manganese chloride, 2; sodium ascorbate, 10; glucose-1-phosphate, potassium salt, 0·3; sodium phosphate *p*H 7·5, 5; adenosine diphosphate, 2; and triphosphopyridine nucleotide, 2. The reaction was carried out at 20° C. for 30 min.; gas phase, argon. In treatments 3 and 4, 10 micromoles sodium bicarbonate, containing $^{14}CO_2$, were injected at the beginning and the reaction vessels were illuminated or left in the dark, respectively. In treatment 1, the reaction mixture was first illuminated without the addition of bicarbonate. After 30 min., the particles containing chlorophyll were removed by centrifugation, and the chlorophyll-free supernatant fluid was incubated in the dark for 30 min. with 1·5 micromoles cystein and 10 micromoles of sodium bicarbonate containing $^{14}CO_2$. The same procedure was followed in treatment 2 as in treatment 1 except that adenosine diphosphate and triphosphopyridine nucleotide were omitted.

occurred in the complete chloroplast system in the dark (treatment 4).

The products of carbon dioxide assimilation were found to be the same whether it occurred during continuous illumination (Fig. 1) or in the dark, at the expense of assimilatory power generated during a preceding light period (Fig. 2). They included hexose and pentose mono- and di-phosphates, phosphoglyceric acid, dihydroxyacetone phosphate, and small amounts of phosphoenolpyruvate and malate.

Carbon dioxide fixation in the dark was sensitive to cyanide. The inhibition at 10^{-3} *M* cyanide varied between 60 and 80 per cent.

Assimilatory Power from Outside Sources

The conclusion that adenosine triphosphate and reduced triphosphopyridine nucleotide are the components of assimilatory power required by chloroplast enzymes for carbon dioxide assimilation was tested by supplying these substances, in substrate quantities, from external sources instead of generating them in a light reaction. The results are shown in Table 2.

Reduced triphosphopyridine nucleotide, when prepared either chemically, or enzymatically with isocitric dehydrogenase, was, in combination with adenosine triphosphate, as effective in bringing about carbon dioxide assimilation by the chlorophyll-free extract of chloroplasts as the 'assimilatory power' generated by illuminated chloroplasts. The omission of reduced triphosphopyridine nucleotide or its substitution by reduced diphosphopyridine nucleotide cut carbon dioxide fixation approximately in half. No significant fixation occurred when both reduced triphosphopyridine nucleotide and adenosine triphosphate were absent.

Table 2. CARBON DIOXIDE FIXATION IN THE DARK BY A CHLOROPHYLL-FREE EXTRACT OF CHLOROPLASTS, SUPPLEMENTED WITH ADENOSINE TRIPHOSPHATE (ATP) AND REDUCED TRIPHOSPHOPYRIDINE NUCLEOTIDE ($TPNH_2$) OF PHOTOSYNTHETIC AND NON-PHOTOSYNTHETIC ORIGIN

Treatment	$^{14}CO_2$ fixed counts/min.
1. Chlorophyll-free extract + A.P.*	96,000
2. Chlorophyll-free extract − A.P.*	4,000
3. Chlorophyll-free extract + ATP†	43,000
4. Chlorophyll-free extract + (ATP† + $DPNH_2$‡)	50,000
5. Chlorophyll-free extract + (ATP† + $TPNH_2$§)	97,000
6. Chlorophyll-free extract + (ATP† + $TPNH_2$‖)	140,000

Treatments 2–6 were the same as treatment 2 in Table 1, except for the indicated additions.

* A.P. = Assimilatory power, that is, ATP + $TPNH_2$, formed in light by chloroplasts (see treatment 1, Table 1).

† Two micromoles (from animal sources, Sigma Chemical Co.).

‡ $DPNH_2$ = reduced diphosphopyridine nucleotide (2 micromoles) enzymatically prepared, Sigma Chemical Co.

§ 1·4 micromoles, enzymatically prepared with isocitric dehydrogenase. The enzyme itself was without effect on the course of the reaction.

‖ 2 micromoles, chemically prepared, Sigma Chemical Co.

In the dark fixation experiments described so far, reduced triphosphopyridine nucleotide was supplied in substrate quantities, since no provision was made for its regeneration, as would be the case with illuminated chloroplasts. However, carbon dioxide assimilation in the dark also proceeds with a catalytic amount of reduced triphosphopyridine nucleotide if its supply is maintained by an enzymatic reaction catalysing a triphosphopyridine nucleotide-dependent oxidation of an appropriate substrate. Parallel experiments have shown that in addition to the enzymes previously identified[8,9,11], the chlorophyll-free extract of chloroplasts contained glucose-6-phosphate dehydrogenase, 6-phosphogluconic acid dehydrogenase and isocitric dehydrogenase which catalyse, respectively, reactions 3, 4 and 5[29,30].

$$\text{Glucose-6-phosphate} + \text{TPN} \longrightarrow \text{6-phosphogluconate} + \text{TPNH}_2 \quad (3)$$

$$\text{6-Phosphogluconate} + \text{TPN} \longrightarrow \text{ribulose-5-phosphate} + \text{CO}_2 + \text{TPNH}_2 \quad (4)$$

$$\text{D-Isocitrate} + \text{TPN} \xrightarrow{\text{Mn}^{++}} \alpha\text{-ketoglutarate} + \text{CO}_2 + \text{TPNH}_2 \quad (5)$$

Table 3 shows that catalytic amounts of reduced triphosphopyridine nucleotide (0·3 micromole) generated *in situ* by the oxidation of one of three substrates, glucose-6-phosphate, 6-phosphogluconic acid or isocitric acid, were, in combination with adenosine triphosphate, as effective for carbon dioxide assimilation in the dark as substrate amounts of reduced triphosphopyridine nucleotide (2 micromoles) used in previous experiments (Tables 1 and 2). Carbon dioxide fixation was greatly diminished by omitting

Other experimental conditions as in treatment 2 of Table 1.

either adenosine triphosphate or triphosphopyridine nucleotide. Moreover, in the absence of reduced triphosphopyridine nucleotide little, if any, sugar phosphate was found among the products of fixation.

In the experiments represented by Table 3 photosynthesis has been replaced by a chemosynthesis in the sense that the reductant required for carbon dioxide assimilation by chloroplast enzymes was being continuously generated at the expense of a chemical hydrogen donor, a sugar phosphate or an organic acid, instead of light energy. As shown in Fig. 3, the products of this chemosynthesis by chloroplast enzymes are the same as those found during photosynthesis (Fig. 1).

In the present investigation, the chlorophyll-free extract of isolated chloroplasts was the source of all the enzymes required for the dark synthesis of phosphorylated sugars from carbon dioxide. Other cell-free systems have been described as models for photosynthetic carbon assimilation. Racker[31] used for the synthesis of hexose monophosphate a multi-enzyme system in which spinach leaves served as a source or the pentose cycle enzymes. These were supplemented[32] with glyceraldehyde-3-phosphate dehydrogenase and aldolase from rabbit muscle and phosphoglyceric acid kinase from yeast. The reductant was reduced diphosphopyridine nucleotide, rather than reduced triphosphopyridine nucleotide as in our experiments, and was generated either with molecular hydrogen and a diphosphopyridine nucleotide-linked hydrogenase from a bacterial source or with alcohol and an alcohol dehydrogenase from yeast. Fager[33] prepared from whole spinach leaves a protein fraction which fixed carbon dioxide not to the level of sugars but as phosphoglyceric and pyruvic acids. The rate of carbon dioxide fixation was increased when this fraction was illuminated in the presence of chloroplast fragments; in his system the addition of diphospho- or triphospho-pyridine nucleotides had no effect, whereas that of adenosine triphosphate was inhibitory to carbon dioxide fixation in both light and dark.

General Considerations

In whole cells the light and dark phases of photosynthesis were investigated by techniques of intermittent illumination and experiments on induction phenomena[2,34–38]. Evidence began to accumulate[37,39,40], and was later strengthened by experiments with radiocarbon[41–45], in support of the view that carbon assimilation occurs during the dark phase of photosynthesis. Pre-illuminated cells retained for a short time, measured in minutes[42–44] or seconds[45], the ability to fix carbon dioxide afterwards in the dark. Benson and Calvin[42,43] interpreted this dark fixation as having been accomplished by a "reducing power" formed during the pre-illumination period, whereas Gaffron *et al.*[45] considered that pre-illumination produced an acceptor which was carboxylated during the dark carbon dioxide 'pick-up'. No experimental evidence was adduced in either case for the identity of the postulated short-lived product(s) of the photochemical reactions.

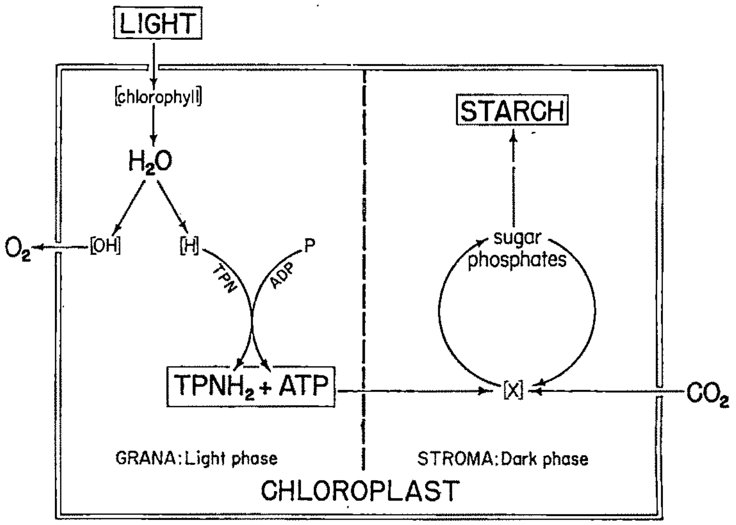

Fig. 4. Scheme for photosynthesis by isolated chloroplasts. In the light phase, photolysis of water, catalysed by 'grana', results in the evolution of oxygen and the generation of assimilatory power comprising two components: reduced triphosphopyridine nucleotide ($TPNH_2$) and adenosine triphosphate (ATP). In the dark phase, assimilatory power is used by the enzymes in the 'stroma' for the assimilation of carbon dioxide in reactions independent of light

Photosynthesis by isolated chloroplasts was found to lend itself to a physical separation into a light phase concerned with the generation of a stable assimilatory power, chemically defined as adenosine triphosphate and reduced triphosphopyridine nucleotide, and a dark phase during which the assimilatory power is used for carbon assimilation. A diagrammatic scheme of photosynthesis by chloroplasts, based on these findings, is shown in Fig. 4.

The separation of the light and dark phases of photosynthesis in isolated chloroplasts was aided by the association of each phase with a different portion of the chloroplast. The dark phase of photosynthesis was found to be associated solely with the water-soluble chlorophyll-free extract. The light phase was, as would be expected, localized in the 'grana' fraction which contains the chlorophyll pigments. However, the light phase appears to involve, in addition to the 'grana', some 'stroma' factors. At least one of these, the pyridine nucleotide-reducing factor[26,21,27], must be present if the generation of 'assimilatory power' is to occur in the light.

The CO_2-fixing enzymes are loosely associated with the chlorophyll pigment system in chloroplasts, and in photosynthetic bacteria[46] do not appear to have formed any structural association at all. Why then should carbon assimilation continue to be regarded as an essential part of photosynthesis? Carbon dioxide assimilation by chloroplast enzymes can be studied as a dark process independent of the photosynthetic pigment system. The basic feat of photosynthesis, the conversion of light into useful chemical energy, is accomplished here through the formation of adenosine triphosphate and reduced triphosphopyridine nucleotide (equations 1 and 2). In the living cell these are present in catalytic amounts and hence the trapped light energy is usually, although perhaps not always[21], stored by coupling their formation with carbon assimilation. *In vivo*, the photochemical phase of photosynthesis is therefore tightly bound to carbon assimilation. But in isolated chloroplasts, adenosine triphosphate and reduced triphosphopyridine nucleotides can be made to accumulate in substrate amounts and their accumulation is a direct measure of the photosynthetic process. Here photosynthesis may be considered as having been completed before carbon assimilation begins. The key problem of photosynthesis, the conversion of light into useful chemical energy, need not, therefore, be enmeshed in the dark enzymatic reactions responsible for the synthesis of carbohydrates.

We are indebted to Dr. F. R. Whatley for the preparation of chloroplasts. We were aided in this investigation by grants from the U.S. Public Health Service and the Office of Naval Research.

THE JOHN CURTIN SCHOOL OF MEDICAL RESEARCH, AUSTRALIAN NATIONAL UNIVERSITY

ON March 27, Sir Howard Florey, in the presence of the Prime Minister of Australia, the Right Hon. R. G. Menzies, opened the new building of the John Curtin School of Medical Research at the Australian National University in Canberra. The National University was founded in 1946 as a national centre for research and research training, initially in the fields of physical sciences, medical sciences, and the social sciences.

There had long been complaints in Australia that many of the most able scientists left the country because of the greater attractions in universities and research institutions in Great Britain. Such complaints applied more to the medical sciences than to other natural sciences, for which the large and varied laboratories of Commonwealth Scientific and Industrial Research Organization provided first-class facilities, whereas the only medical research institute in Australia with an international reputation was the relatively small Walter and Eliza Hall Institute in Melbourne.

In a report to the Commonwealth Government in 1944, Sir Howard Florey suggested that a national institute for advanced medical sciences should be set up in Australia, and the John Curtin School of Medical Research, established as an integral part of a University devoted to research and research training, is the result of this suggestion. Sir Howard Florey was intimately associated with the development of the School from the time of his report until 1955, and the building he opened on March 27 is a monument to his inspiration and drive. There were no laboratories in Canberra in 1948 when the first professor was appointed, so the departments were started in laboratory space generously lent by several institutions—biochemistry at the Commonwealth Serum Laboratories, Melbourne; medical chemistry at the Wellcome Research Institution in London; microbiology at the Walter and Eliza Hall Institute in Melbourne; experimental pathology in Sir Howard Florey's Laboratories in Oxford and physiology in the University of Otago in New Zealand.

In 1951, temporary laboratories were built in Canberra, and these were occupied between 1952 and 1957, when the departments transferred to the present building (Fig. 1). This is a brick building about 170,000 sq. ft. in floor area. It is built in an H-shape, with four wings for laboratories (which are mainly confined to the upper two floor-levels) and a central spine housing lecture theatre, seminar rooms, offices, tea rooms and library. The lower levels of the building house many of the service departments: store, photography, media kitchens, mechanical plant, etc. In addition, there are two animal houses, each

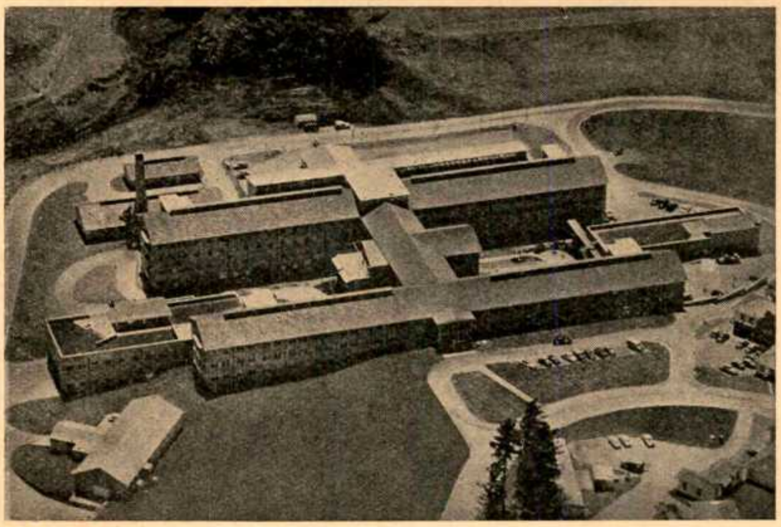

Fig. 1. The John Curtin School of Medical Research, Australian National University, Canberra

of some 7,000 sq. ft. floor area—one for non-infected and the other for infected animals; an animal-breeding establishment some four miles away, and a large light-engineering workshop.

The laboratory wings have on the south side laboratories 20 ft. deep and on the north side service rooms (hot rooms, cold rooms, etc.) and studies 14 ft. deep. The laboratory layout on each floor-level is adapted to the needs of the particular department, but within the departments it follows a standard plan.

At present there are five departments—biochemistry, experimental pathology, medical chemistry, microbiology and physiology. Prof. A. H. Ennor, head of the Department of Biochemistry, is also dean of the School. His department comprises nine staff and five research students, and is concerned principally with enzymology of phosphorylated guanidines. Prof. F. C. Courtice, well known for his researches on physiology of lymph flow, etc., has just been appointed to the chair of experimental pathology. Prof. Adrien Albert heads a group of seven research workers and two research students in the Department of Medical Chemistry. His work on heterocyclic chemistry is familiar to most British scientists, and he now has greatly increased facilities for this work. Prof. F. Fenner, with seven staff members and eight research students, is investigating various aspects of animal virology, principally with the pox viruses and influenza viruses. The Department of Physiology, headed by Prof. J. C. Eccles, specializes in neurophysiology. Prof. Eccles is at present president of the Australian Academy of Science. His distinguished investigations made by micro-electrode methods are widely known, and he is assisted in this work by seven staff members and four research students.

At present the total research staff is about forty and there are some twenty Ph.D. students; but the John Curtin School of Medical Research is still in the process of growth, both in the sense that several new departments will be developed over the next few years to fill in gaps in the present structure, and in the development of each individual department. The new building just opened by Sir Howard Florey provides excellent facilities in a wide range of the medical sciences and already the School is established as a research institution well known throughout the world.

HIGH ENERGY NUCLEAR PHYSICS

THE annual international conference for 1958 on High-Energy Nuclear Physics, which was held in Geneva during June 30–July 5 under the sponsorship of the International Union of Pure and Applied Physics was the successor to those that have been held annually in Rochester, New York, for the past seven years. Over these years the size and duration of the Conference had increased from a small one-day meeting to a full week of intensive sessions recognized as the most important conference on high-energy physics of the year. It was the general opinion at Rochester in 1957 that the volume of effort and the number of contributions had grown to such an extent that the traditional system whereby each contributor presented the results of his experiments had become unworkable and, short of the undesirable step of limiting the scope of the conference still further, it was evident that some new method of presenting the material had to be tried. This year at the European Centre for Nuclear Research (C.E.R.N.) the conference was divided into ten half-day sessions and all contributions in a particular field were presented to the conference by one person, the rapporteur, whose job it was to introduce the subject and to present and to explain the significance of the results obtained. The talks by the rapporteurs were expected to take up approximately half the session and the other half was left for discussion or for the presentation of special papers which did not fit well into the rapporteur's general scheme. The success of this procedure depends very much on the rapporteur. Contributors were asked to submit their papers to him some four weeks before the plenary sessions. Organizing sessions were arranged on the three days preceding the conference proper to enable participants to meet their rapporteur and if necessary to discuss their contributions with him. As an additional preliminary rapporteurs were asked, prior to the Conference, to provide participants with a reading list which would serve as an introduction to the subjects.

The general opinion at the end of the Conference was that the new method of presentation had been enough of a success for the method to be tried again. It was most successful where the rapporteurs, having been selective in the choice of their material, had leisure to present it in a critical way and not merely as a report of a large number of different experiments.

One of the main disadvantages of the rapporteur system lies in the fact that the reports are very concentrated. Contributors tended to remain anonymous with this method of presentation and it was felt that some advantage would have been gained if mimeographed sheets had been made available before each session, giving the title and authors of the contributions so that further details could the more easily have been sought from them afterwards. Tables of important results would also have proved most valuable. The next International Conference is expected to be held in Moscow in July 1959, where the organizing sessions are to be enlarged to enable contributors to present their results in greater detail to the rapporteur and to others working in the same field.

The first plenary session was devoted to experimental and theoretical reports on nuclear structure. Most of the results reported concerned high-energy electron scattering. Both the charge and magnetic-moment scattering of electrons by protons differs markedly from that obtained on the assumption of a point particle. The results suggest a root-mean-square value for the charge radius equal to that for the magnetic moment, both being equal to 0·8 fermi (1 fermi = 10^{-13} cm.) for the proton, and a similar value for the radius of the neutron magnetic moment distribution, obtained by a comparison of electron–proton and electron–deuteron scattering. The charge core of the neutron appears to be zero at low momentum transfers although a value of 30 per cent of that for the proton at large momentum transfers is not ruled out by the limits of accuracy of the measurements. The different charge radii for the neutron and proton raise the question whether charge symmetry holds or whether the interpretation of the results based on quantum electrodynamics is correct. A word of caution was given by Hofstadter against reading too much into the results until the accuracy is improved, but nevertheless the theoretical interpretation is in a very confused state.

Experiments with muons which can be compared with similar scattering experiments with electrons may be expected to shed more light on the structure of the nucleon during the next few years. The plea for some experimental information on the electromagnetic structure of the pion may have to wait a little longer.

In the two sessions devoted to the nucleon and its interaction with pions, photons, nucleons and antinucleons, some uncertainties which existed at the 1957 Conference in Rochester appear to have been satisfactorily resolved. In 1957 there was evidence that the coupling constant, f^2, obtained from the real part of the forward-scattering amplitude for negative pions via the dispersion relation was very low. However, new measurements of the negative pion–proton scattering cross-section have been made which bring the calculated value of f^2 into line with other determinations. A final value of $f^2 = 0\cdot0885 \pm 0\cdot002$ was quoted. The experimental and theoretical values for the 'Panofsky ratio' are now also believed to be in good agreement although this was only clarified after considerable discussion. Evidence for the Fermi set of phase shifts is also now well established. An excellent review of the theoretical position was given by Chew. The subject of greatest interest during the past year has been the dispersion relations and the possibility of their violation. However, the theoretical studies that have been made confirmed the belief that the Goldberger relations for forward scattering have a very general basis. Another development was a new type of dispersion relation which allowed a precise determination of the pion coupling constant. A basic question which continues to be obscure is whether it is possible in terms of the pion and nucleon masses and the coupling constant to predict the position of the (3/2, 3/2)-resonance and the small size of the non-charge-exchange S-wave scattering. In the GeV.-region, optical models of the pion-scattering results suggest that the pion–pion interaction is important.

The dispersion relation approach has also been applied to the problem of photon–nucleon scattering and the agreement of theory with experiment is improving. A great deal of discussion centred on the results obtained at Cornell and the California Institute of Technology, where photo-production processes appeared to show a resonance behaviour corresponding to excited states of the nucleon at 300, 600 and 1,000 MeV. The discussion was not conclusive.

There was also much discussion on the possible origin of the spin-orbit interaction introduced into the phenomenological nuclear potential by Gammel and Thaler and by Marshak and Signell last year. The large antinucleon–nucleon total cross-sections have, in fact, now been reasonably explained using a Signell and Marshak type of potential, and although this is again a purely phenomenological approach the feeling has subsided that the large experimental values for the antinucleon–nucleon cross-section would require a major departure from the Yukawa picture.

It is almost traditional now for the discovery of yet another new particle to be announced at the annual conference. This year the anti-Λ^0-particle was reported to have been observed in a two-prong-star event at Berkeley, decaying via a positive pion and antiproton, with a Q value of $35 \, {}^{+2\cdot6}_{-0\cdot9}$ MeV. In addition, a cosmic-ray event in a two-level cloud chamber belonging to the Pic du Midi group of the École Polytechnique has provided evidence for the cascade Ξ^0-particle. During the past year, six groups have been doing experiments to establish evidence for the particle of 500 electron masses which was first reported by Alikhanian some years ago. The general conclusion was that its existence was not yet firmly established. More experiments are still being carried out.

In the production of the Λ^0-particle in the pion–nucleon interaction, within the limited accuracy of the measurements, parity is conserved. Existing data are also in agreement with the conservation of isotopic spin. The interaction of K-mesons is explained most reasonably by a pseudo-scalar meson of spin zero. Below 100 MeV. in K^- interactions there is no evidence for anything other than S-waves being important.

One session was devoted to special topics, of which the most interesting related to the origin of the mass of the electron and whether it was entirely electromagnetic or not. An associated problem was the question of the large mass of the muon. It was suggested that a precise measurement of the magnetic moment of the muon would be of great value in order to check whether there was any departure from the value predicted by electromagnetic theory.

Perhaps the most remarkable achievement of the year has been the effort that has gone into the study of parity non-conservation in weak interactions. The two-component neutrino theory[*] is now well established. Parity non-conservation appears to be complete and no deviation from invariance under time reversal is observed. There are, however, some points which are not clearly understood. For example, non-conservation of parity is observed in hyperon decay where no neutrino is involved. The magnitude of the $\pi \rightarrow e + \nu$ and $\pi \rightarrow \mu + \nu$ branching ratio provoked much discussion, and it was emphasized that this could prove a very critical test of the universal Fermi interaction. The interaction is now well established as '$V - A$' (vector, axial vector) but the reason why it should be so is still unknown. The beta-decay of the Λ-particle is another puzzle. The present experimental results set the limit for this mode of decay at not more than 1 in 1,000 and they are, in fact, consistent with zero. A new value for the Michel parameter, $\rho = 0{\cdot}735 \pm 0{\cdot}022$, was reported from Berkeley in better agreement with that expected theoretically (0·75). However, the errors quoted are purely statistical and when systematic errors are allowed for, this value may again be changed.

In the case of non-leptonic modes the bulk of the new information concerned the decay modes and the branching ratios for Λ^0 and K^0 and the life-times of Λ^0, K^0 and $\Sigma^\pm$. From a study of the angular distribution of the decay with respect to the production direction it appears possible to assign to both the Λ^0 and Σ^- particles a spin of one-half. One new experimental technique, the scintillation chamber, was discussed at a small separate session. It may prove to be a useful new development.

The organizers at C.E.R.N. are to be congratulated on their efficient handling of the conference. The discussions were recorded on tape, typed and in the hands of those concerned for correction within twenty-four hours. The full proceedings of the conference including the talks by the rapporteurs are expected to be available to the participants by October.

G. H. STAFFORD

NEWS and VIEWS

Entomology and Parasitology at Liverpool : Prof. R. M. Gordon

PROF. R. M. GORDON, who is to retire from the Dutton and Walter Myers chair of entomology and parasitology in the University of Liverpool, acquired an interest in parasitic and arthropod-borne diseases during his army service in Serbia after his qualification at Trinity College, Dublin. Joining the staff of the Liverpool School of Tropical Medicine, he worked in the School's laboratories on the Amazon and in Sierra Leone. He relinquished the directorship of the latter laboratory in 1937 to occupy the chair in entomology in Liverpool; later the chair in parasitology was amalgamated with this. For the past twenty years, in spite of heavy teaching and administrative duties, Prof. Gordon has continued to engage in active research. Primarily a naturalist, not a systematist, he has maintained a 'zoo' of living parasites and their vectors rather than a collection of 'specimens' in his department. Many workers have achieved distinction following the sound training and wide practical experience gained in his department. Early in his career Dr. Gordon, with D. B. Blacklock, first demonstrated immunity to metazoan parasites. The meticulous detail of his work is to be seen in some remarkable micro-cinematograph recordings of the penetration of the mouth-parts of blood-sucking arthropods and their feeding methods. Latterly, the filarial infections have claimed his attention; he largely has originated and directed the helminthiasis research units now working on this problem in West Africa. Prof. Gordon's achievements have entailed much work on committees, which he serves wholeheartedly. The Royal Society of Tropical Medicine and Hygiene conferred its Chalmers Medal on him in 1937; recently it made him its president.

Dr. W. E. Kershaw

DR. W. E. KERSHAW, who is to succeed Prof. R. M. Gordon, joined the staff of the Liverpool School of Tropical Medicine in 1945 as a lecturer in parasitology. He served afloat, and later as a pathologist ashore, with the Royal Navy during the Second World War, and while stationed in Ceylon his contact with the parasitic infections of man determined his future interests. Dr. Kershaw's interests have primarily centred on the helminthiases, and in particular the filariases. His work on the latter has been original and outstanding, and he has travelled widely on field studies in this context. In 1955 he was awarded the Chalmers Medal of the Royal Society of Tropical Medicine particularly for his work in this subject, and his services are in frequent demand at conferences on it in Great Britain and elsewhere. Dr. Kershaw continues an active association with the Navy as a surgeon-commander, an activity which affords opportunity for a more clinical application of his abilities, and which should be of benefit to the Service to which he is proud to belong.

Geology at Southampton : Dr. F. Hodson

DR. F. HODSON's appointment to the newly created chair of geology at Southampton will give pleasure to geologists at home and abroad, particularly the younger generation. Trained in geology at the University of Reading, Dr. Hodson had the advantage (many forward-seeing geologists would say a necessity) of coming to the subject from two basic sciences. Initially a works chemist and by inclination a zoologist, he was well equipped to profit from university life and ultimately to undertake those researches in Namurian stratigraphy and palæontology for which he has become widely known. His work has shed new light on the Upper Carboniferous rocks of several key areas in western Europe: particularly western Eire, Belgium and the Valenciennes coalfield. In collaboration he has contributed to Jurassic stratigraphy and palæontology. At Reading Dr. Hodson has built up a flourishing Carboniferous research school, devoted mainly to opening up the exciting territory of western Eire. He will take to Southampton not only a tremendous enthusiasm and deep conviction that the 'research outlook' should dominate undergraduate teaching, but also an all-round fitness to foster the several facets of geology and to maintain a sensible balance between competing interests. The University of Southampton may confidently look forward to the future growth and vigour of its Geology Department, and to whole-hearted participation by its first professor of geology in the progress of this new seat of learning.

Applied Mathematics at Aberystwyth : Prof. T. V. Davies

Thomas Vivian Davies, since 1954 reader in mathematics at King's College, London, has been appointed to the chair of applied mathematics at University College, Aberystwyth, in succession to Prof. G. J. Kynch (see *Nature*, 180, 69 ; 1957). He received his undergraduate training in mathematics under Prof. V. C. Morton and the late Prof. T. Lewis at Aberystwyth, specializing already at that stage in fluid dynamics. During the War he worked with the Ministry of Supply and the Meteorological Office; since 1946 he has been on the staff of the Department of Mathematics at King's College, London. He went to the United States to carry out meteorological research in 1951, first at the Institute for Advanced Studies at Princeton and later at the Massachusetts Institute of Technology. Mr. Davies has been stimulated principally by geophysical problems : he has developed a new theory of gravity waves of finite amplitude, and has investigated the forced fluid motion and the stability of rotating liquids which are subject to differential heating. More recently, his work has been in the field of magnetohydrodynamics, and in pure mathematics his interests centre on non-linear differential equations. Mr. Davies has served as a member of the Council of the Royal Meteorological Society and of the Meteorological Research Council. His colleagues at King's College, London, have increasingly learned to respect him for his outstanding gifts as a teacher, for his no less inspired success as an originator and director of research in fluid dynamics and, by no means least, for his unassuming friendliness, his quiet efficiency and his other excellent personal qualities. In common with his many other friends, they wish him well in his new sphere of responsibility.

Pure Mathematics at Birmingham : Prof. P. J. Hilton

Dr. P. J. Hilton, who has recently been appointed Mason professor of pure mathematics in the University of Birmingham, in succession to Prof. C. A. Rogers (see *Nature*, 181, 1378 ; 1958), is a graduate of Oxford, where he was a scholar of Balliol College. After taking his degree in 1947 he held lectureships in the Universities of Manchester and Cambridge until he returned as senior lecturer to Manchester in 1955. His research interests have always been in topology, more particularly in homotopy theory, and its recent developments by the methods of homological algebra : he is the author of a Cambridge Mathematical Tract on homotopy. Dr. Hilton has many contacts with European universities, and was appointed by the Royal Society as delegate to the recent mathematical congress in Roumania. He has shown by his talks to radio and other audiences his interest in all sides of the problems of university teaching, and both he and the University of Birmingham are to be congratulated on this appointment.

Foreign Members of the Academy of Sciences of the U.S.S.R.

At a general session on June 20 the following were elected foreign members of the Academy of Sciences of the U.S.S.R. : *Belgium*, Prof. Z. M. Bacq (biology) ; *Bulgaria*, Prof. G. Nadzhakov (physics and mathematics) ; *Canada*, Prof. E. Steacie (chemistry), Prof. W. Penfield (neurophysiology) ; *China*, Prof. Lee Ssu-Kwang (geology and geography), Prof. Kuo Mo-Zso (history) ; *Korea*, Prof. Pek Nam Yu (history) ; *Czechoslovakia*, Prof. F. Šorm (chemistry) ; *Denmark*, Prof. K. V. Linderstrøm-Lang (biology) ; *France*, Prof. Louis de Broglie (physics), Prof. Louis Néel (physics) ; *German Democratic Republic*, Prof. G. Hertz (physics), Prof. M. Volmer (chemistry) ; *Great Britain*, Prof. J. D. Bernal (physics), Sir Cyril Hinshelwood (chemistry), Prof. C. F. Powell (physics) ; *Hungary*, Prof. I. Rusznyak (biology) ; *India*, Prof. P. C. Mahalanobis (statistics and economics) ; *Italy*, Prof. E. Amaldi (physics), Prof. B. R. Bandinelli (history) ; *Japan*, Prof. S. Kaya (physics) ; *Poland*, Prof. T. Kotarbinski (philosophy) ; *Roumania*, Prof. T. Savulescu (biology) ; *Sweden*, Prof. H. Alfvén (physics), Prof. K. M. B. Siegbahn (physics) ; *Switzerland*, Prof. L. Ruzicka (chemistry) ; *United Arab Republic*, Prof. A. R. Tourky (chemistry), Prof. I. Khalil (literature) ; *United States*, Prof. L. Pauling (chemistry), Dr. D. Bronk (biology) ; *Yugoslavia*, Prof. P. Savić (chemistry).

Royal Society Research Studentships

The Council of the Royal Society has awarded Mr. and Mrs. John Jaffé Donation Studentships in original scientific research from October 1 to Dr. E. A. Magnusson to continue his study of the modification of atomic orbitals in bond formation in the Department of Chemistry, University College, London, and to Dr. Jennifer Wildy to work on the biosynthesis of the protein and hæm components of hæmoglobin in the Department of Chemical Pathology, University College Hospital Medical School.

Nutrition Society of Canada

A meeting of persons interested in nutrition research was held in Ottawa on October 7, 1957, to discuss the formation of a nutrition society. A provisional committee was appointed to prepare a list of founding members and to draft a constitution. On June 8 a formal meeting took place in Queen's University, Kingston, Ontario. A membership of ninety was accepted, a constitution adopted, and the society was named the Nutrition Society of Canada. Membership is restricted to persons concerned with the scientific aspects of nutrition. Officers of the Society are : *President*, E. W. McHenry (Toronto) ; *Vice-President*, E. W. Crampton (Ste. Anne de Bellevue) ; *Secretary*, George H. Beaton (Toronto) ; *Treasurer*, J. A. Campbell (Ottawa) ; *Members of Council*, D. H. Copp (Vancouver), W. W. Hawkins (Halifax), L. B. Pett (Ottawa). The Society intends to hold annual meetings.

Aerial Geophysical Survey of Cornwall

In a written answer to a question on July 15 regarding the aerial geophysical survey of south-west Cornwall made last year for the Atomic Energy Authority, Mr. H. Nicholls, Parliamentary Secretary to the Ministry of Works, as representing the Lord President of the Council, said that the Department of Scientific and Industrial Research has recently published a brief description of this air-borne survey made by the radiometric method. A scientific appraisal of the work will be presented in a paper at the Second International Conference on the Peaceful Uses of Atomic Energy to be held at Geneva early in September and will be published in the Proceedings of the Conference. Ground investigations are continuing in Cornwall and it will be some time before all data recorded from the air have been assessed.

Design in Industry

MANY interesting suggestions concerning the education and training of designers for the furniture, pottery, printing and textile industries are contained in "The Training of Designers for Industry" (pp. vii+50. Federation of British Industries, 21 Tothill Street, London, S.W.1, 1957. 3*s*. 6*d*.). This is the report of a one-day conference between industrialists and educationists, organized under the auspices of the Federation of British Industries and held in London on September 24, 1957. The booklet includes the opening address by Sir Edward Boyle, Parliamentary Secretary to the Ministry of Education, and reports by the chairmen of the five discussion groups on important points made in the course of the conference, together with a summing-up by Sir Ernest Goodale, chairman of the Federation's Industrial Art Committee. It also includes the memoranda circulated before the conference as bases for the group discussions.

National Science Foundation Programme for Atmospheric Sciences

AN Atmospheric Sciences Programme is being established by the U.S. National Science Foundation as a result of recommendations by the President's Committee on Weather Control and the Committee on Meteorology of the National Academy of Sciences —National Research Council. The new programme will deal with meteorology, including not only the more conventional type of meteorological research, but also energy transfer processes between earth, sea and air; turbulent flow of gaseous fluids; heat exchange processes; upper atmosphere studies (that is, above the level of conventional meteorological work); atmospheric chemistry; and general circulation problems of the atmosphere and oceans. Attention will also be given to the field of cloud physics, especially the physics of precipitation, where much basic research must be pursued before the possibilities of controlling or modifying weather can be evaluated. The programme director will be Dr. Earl G. Droessler, who has wide experience in administration and co-ordination of military scientific research and development, and in research in meteorology and glaciology.

Agricultural Meteorology in India

A SPECIAL issue of the *Indian Journal of Meteorology and Geophysics* was published in December 1957 in honour of the silver jubilee of the Agricultural Meteorology Division of the India Meteorology Department. The importance of the scientific study of the relations between crops and weather has long been recognized, notably early in this century in Britain by Sir Napier Shaw, and the International Meteorological Organization formed its Commission for Agricultural Meteorology in 1913. It is, however, only in relatively recent years that stations specifically equipped and staffed by meteorological physicists have been set up to make detailed micrometeorological and related observations. India, under Sir Charles Normand's tenure of the post of Director-General of Observatories, was one of the first countries to establish such a unit. The Division was formed at Poona in 1932 and placed under Dr. L. A. Ramdas, who remained in charge until 1953.

The Central Agricultural Meteorological Observatory is on the farm of the Agricultural College at Poona. It is equipped with instruments for observing the micro-structure of the atmosphere up to 35 ft. in the free air and within crops, and also radiation, evaporation, soil properties and plant temperatures. The Division also controls less detailed meteorological work at some forty other experimental farms in India, and maintains weekly charts of the relevant weather elements and of the progress of crops all over India. The major work now in progress is concerned with the water requirements of plants, the relation between weather and the incidence of disease and pests and the preparation of crop–weather calendars for the guidance of regional meteorological centres in the preparation of the weather forecasts for the farmers' weather bulletins. It was at this Division that the observation was first made that under clear sky at night the air just above ground is often colder at a height of 5–15 cm. than at the ground itself. This observation, scarcely credited for a time, has been repeated at several places elsewhere with other types of apparatus but is still not fully explained.

University College, London: Report for 1956–57

THE annual report of University College, London, for 1956–57 (pp. 89. London: University College, 1958) includes the report of the chairman of the College Committee and the provost, together with those of the Students' Union, the Bartlett School of Agriculture and the Slade School of Fine Art, and lists of publications of members of academic departments. Of the 3,574 students (including 795 part-time) 755 were postgraduate (239 part-time). Some 589 undergraduates and 318 postgraduates were in the faculty of science and 206 undergraduates and 66 postgraduates in engineering. The year was the last of the old quinquennium, which closed with a deficit of £2,455, and the report, commenting on the absence of general funds for research, records the severe disappointment with the grant from the University Grants Committee for the new quinquennium: that of £1,165,000 for 1957–58 will permit no academic expansion and will necessitate a substantial cut in maintenance. Capital expenditure of £280,000 was concentrated on the new Biological Sciences Block, but the planning of the first stage, to cost £500,000, of the new Engineering Building is well advanced. In the Department of Chemistry investigations of the mechanisms of reactions in solution have recently been correlated with studies of reactions in the gas phase, and some main lines of investigation have been greatly facilitated by the installation of a nuclear magnetic resonance apparatus through the generosity of the Wellcome Trust. In the Department of Physics assembly of the microtron has proceeded satisfactorily (see *Nature*, June 21, p. 1726), and the new high-pressure cloud chamber has been assembled and tested.

Arthur D. Little Research Institute

THE first annual report of the Arthur D. Little Research Institute (Inveresk, Midlothian), inaugurated on March 22, 1957, records that on December 31 the Institute's staff totalled twenty-two, of whom twelve were qualified scientists. The three projects under investigation at that date embraced a general study of linear polymers of spatially regular structures, including the mechanism and kinetics of formation of such polymers and their physical properties; a study of sucrose, starting with the sodium sucrates and their condensates with chloro compounds; and a corrosion project including an investigation of the effect of the structure of organic additives, with particular emphasis on physical and chemical inhibition mechanisms around the neutrality point. Five papers published during the year are listed, as well as the titles of six others submitted for publication.

Climatic Tables

The Meteorological Office receives a very large number of inquiries for climatic data for places in all parts of the world from industrial firms and others. Many of these inquiries relate to temperature, humidity and precipitation and it has been the practice to prepare and sell mimeographed tables of these elements to inquirers. The data most required are now being published (Air Ministry: Meteorological Office. Tables of Temperature, Relative Humidity and Precipitation for the World. London: H.M. Stationery Office, 1958) in six parts as follows: (1) North America, Greenland and the North Pacific Ocean; (2) Central and South America, the West Indies and Bermuda (to be published shortly); (3) Europe and the Atlantic Ocean north of 35° N. (to be published shortly); (4) Africa, the Atlantic Ocean south of 35° N., and the Indian Ocean; (5) Asia; (6) Australia and the South Pacific, Antarctica. Each part gives monthly values of the following information for a carefully selected and representative set of several hundred observing stations: temperature: average daily maximum and minimum, average highest and average lowest in each month, absolute maxima and minima; relative humidity: average values, varying times but selected as far as possible to give night and midday values; precipitation: average monthly fall, maximum in 24 hr., average number of days of 0·01 in. or more. Each part has a map showing the stations, an index, and bibliography of sources, and the latitude, longitude and height of each station is given in the tables. Great care has been taken in collaboration with the British Government's Permanent Committee on Geographical Names to give place-names under all the forms by which each is likely to be known, a matter of no small difficulty for places in the Far East and U.S.S.R. All six volumes are also being made available bound into one book.

The Absorption Spectrum of Water Vapour

In his paper, "Das Spektrum des Wasserdampfes" (*Ber. Deutsch. Wetterdienstes*, Nr. 44, 6; 1958), W. Regula gives a valuable summary of the theory of, and experimental information on, the absorption spectrum of water vapour over the wave-length range 1·35 cm. to 300 A. The positions of the absorption bands are given in tables under the type of process responsible. The intensities are indicated qualitatively (strong, medium, weak) in most instances. The paper may be useful to physicists as well as meteorologists.

Spectrum of the Night Sky

In a paper on the altitude of atmospheric layers emitting the lines [O I] 5577 A., [O I] 6300 A. and [Na I] 5892 A. (*Pub. de l'Observ. de Haute-Provence*, 3, No. 36; 1957), Jean Dufay and Tcheng Mao-Lin have re-examined all the observations of the bright lines in the night-sky spectrum. Following the method described by Barbier, corrections for extinction and for scattered light have been made. Taking into account only the molecular scattering and the absorption by atmospheric ozone, the following equivalent heights are obtained: λ, 5577 A., *z*, 195 km.; λ, 5892 A., *z*, 200 (or 230) km.; λ, 6300 A., *z*, 280 km. If, however, a thin layer of haze is present in the lower atmosphere, producing at the zenith the additional optical density $D_0(v) = 0{\cdot}0050$, these heights may be reduced to 170, 170 (or 200) and 250 km., respectively. The uncertainty arising from a selective absorption by water vapour and by oxygen molecules, chiefly from the emission of the OH band, is also discussed.

Cricket Bat Willow

Salix alba var. *caerulea* is as a timber tree unique in Britain, in that the care lavished on it during (and after) its lifetime is reminiscent more of the practices of horticulture than of forestry. This is the result of the high value of its timber when well grown. Current methods of producing timber of the best quality are fully described in "Cultivation of the Cricket Bat Willow" (Forestry Commission. Bulletin No. 17. Pp. vi+34+33 plates. London: H.M. Stationery Office, 1958. 5*s*. net). Rooted or unrooted 'sets' (cuttings) are planted widely (at least 30 ft. apart), lateral branches are removed early and buds appearing on the main stem are rubbed out before they become woody, to a height of 8 ft. Thus a mature stem 8 ft. long and free of knots is produced, but even so, only the lower part of the trunk may give timber suitable for cricket bats of the highest quality. Rapid growth gives the desired sapwood (heart wood is not used in bat making) with annual rings up to 1 in. in width, and this with a straight grain combined with toughness and ability to withstand compression are all characters looked for in the timber by the bat maker. It is now known that male as well as female trees may combine all these desirable qualities in their wood, but they will be lacking unless the site is carefully chosen, insect pests controlled, and protection from grazing animals afforded, and even then 'stain' may develop in the timber, or water-mark disease (due to *Bacterium salicis* Day) affect the trees, rendering them virtually useless.

Control of Aquatic Weeds

Progress in the control of weeds on agricultural land has not been paralleled by the evolution of reliable methods for the control of aquatic weeds. Present-day practices and the results of recent research in this field are summarized by Aylwin P. Chancellor in "The Control of Aquatic Weeds and Algae" (pp. 20. London: H.M. Stationery Office, 1958. 2*s*. 6*d*. net). Mechanical methods of removing weeds from ponds and lakes are often preferable to chemical means, but for emergent weeds in still or running water the use of growth substances (particularly sodium 2 : 2-dichloropropionate) offers great promise. Sodium arsenite can be used to control submerged weeds in still water and is effective at concentrations that are harmless to fish. Submerged weeds in running water cannot be satisfactorily controlled, while chlorine and copper sulphate, both effective in controlling algae, have the disadvantage of extremely high toxicity to fish. Added to this is the fact that if a heavy growth of algae is killed off, the products of decay and the great reduction in the oxygen content of the water may be undesirable. Treatment in spring or early summer may kill the pioneers of the algal flush of growth so that control without any secondary ill-effect is secured.

American experiments indicate that the concentration of copper sulphate necessary to control some algae (for example, 5·0–10·0 p.p.m. for *Scenedesmus*) may greatly exceed the limits tolerated by fish. Trout, for example, in River Itchin water containing 1 p.p.m. of copper sulphate were killed within 24 hr. Chlorine has similar disadvantages, but rosin amine compounds and 2 : 3-dichloronaphthoquinone both have promise as algicides.

Zoological Nomenclature

THE International Commission on Zoological Nomenclature gives notice that, as from December 6, it will start voting on the following cases involving the possible use of its plenary powers for the purpose specified against each entry. Full details of these cases were published on June 6 in the *Bulletin of Zoological Nomenclature* (16, Part 2) : *Mysis* Latreille [1802–1803], designation of type species for, and validation of neotype for species (*Cancer oculatus* Fabricius, 1780) so designated (Cl. Crustacea, Order Mysidacea) ; (2) *Dactylioceras* Hyatt, 1867, designation of type species for (Cl. Cephalopoda, Order Ammonoidea : Jurassic) ; (3) *gemmascens* Esper [1794] (*Madrepora*), validation of (Cl. Hydrozoa, Order Stylasterina). Comments should be sent as soon as possible in duplicate to R. V. Melville, assistant secretary to the Commission, 28 Park Village East, Regent's Park, London, N.W.1.

A Kerr Cell Electro-Optical Shutter

AN exposure time of 0·01 μsec. is claimed for the Kerr cell electro-optical shutter and improved pulse-generator circuit devised by Avco Manufacturing Corporation's Research and Advanced Development Division (Lawrence, Massachusetts). The cell is of 2 in. square cross-section, and the electric field needed to produce phase rotation of the electromagnetic vector as it passes through a cell filled with nitrobenzene is 10–15 kV./cm., so that for a 5-cm. aperture the pulse generator must deliver a pulse of 50–75 kV. to the Kerr cell plates. The generator consists of a coaxial cable and a spark gap, and the cell is connected directly across the load resistor on the transmission line. Exposure time can be varied accurately from 0·01 to 0·1 μsec. by changing the length of the transmission line. The form of the exposure characteristic is approximately square-wave. The selective absorption polarizing material used for the polarizer and analyser on the cell does not provide a completely opaque shutter in the 'off' position, but a transmission ratio of about 20,000 to 1 is obtained with ordinary stock material. The angle of incident light must be limited to 10 deg. or less from the normal, providing a limiting aperture of about *f*/2·5 and an effective aperture of about *f*/10 in operation of the shutter.

Geochemistry

CERTAIN aspects of migration of the chemical elements in the Earth's crust during geological times are discussed by A. A. Saukov (*Priroda*, 2, 10 ; 1958). While the majority of migration processes may be considered to be of a non-directional character, certain processes may give rise to directional types of migration. Thus, the gradual diminution of the quantities of radioactive elements in the Earth and a consequent diminution of the thermal energy of radioactive source may have affected the intensity of metamorphism and magmatism during the geological history. Also, one may consider that the emergence and development of the biosphere has greatly affected the nature and the intensity of migration of the elements, which not only determine the 'directed' accumulation of such organogenic deposits as, for example, coal, bitumen and limestone, but also lead to the accumulation of free oxygen in the atmosphere. This, in its turn, may have affected the behaviour of iron compounds present in the hydrosphere, by a widespread precipitation of the oxidized ferric forms, so prevalent in the widespread iron ore deposits formed in the Pre-Cambrian metamorphic rocks.

National Science Foundation Grants for Science

THE National Science Foundation awarded 246 grants totalling 4,720,545 dollars during the quarter ending March 31, 1958, for the support of basic research in the sciences, for conferences in support of science, for exchange of scientific information, for short-term research by medical students, and for training of science teachers. This is the third group of awards to be made during the current fiscal year. During the first two quarters, awards totalled almost 20·5 million dollars. The research fields included are astronomy, chemistry, biology, physics, earth sciences, engineering sciences, mathematical sciences and social sciences.

Society for Applied Bacteriology

AT the recent annual meeting and summer conference of the Society for Applied Bacteriology, held in Bristol, the following officers of the Society were elected : *President*, Mr. D. A. McKenzie ; *Hon. Secretary*, Mr. G. Sykes (Boots Pure Drug Co., Ltd., Microbiology Division, Standards Department, Nottingham) ; *Hon. Treasurer*, Mr. G. Elis Jones ; *Editor-in-Chief*, Dr. S. E. Jacobs ; *Editor*, Dr. C. A. E. Briggs ; *Hon. Publications Manager*, Mr. A. H. Walters ; *Hon. Advertising Manager*, Mr. E. J. Mann ; *Committee*, Dr. Eve Billing, Mr. N. J. Butler, Prof. E. L. Crossley, Dr. J. G. Davis, Dr. N. R. Knowles, Dr. Jane Meiklejohn, Mr. C. A. Scarlett, and Dr. M. Woodbine.

Darwinism and the Study of Society

To mark the centenary of "The Origin of Species", a conference, organized by the Social Sciences Research Centre of the University of Edinburgh, will be held in Adam House, Edinburgh, during April 8–10, 1959. The proceedings will be divided into six sessions, as follows : (1) "Darwin's Place in the History of Thought", Prof. B. Willey (Cambridge), "The Intellectual Background during Darwin's Student Years in Edinburgh", Mr. G. A. Shepperson (Edinburgh) ; (2) "Darwinism and Human Society in Retrospect", Prof. Lancelot Hogben (Birmingham), "Natural and Social Selection", Dr. W. Stark (Manchester) ; (3) "Genetic Determinants of Human Behaviour", Prof. C. H. Waddington (Edinburgh) ; (4) "Social Evolution", Prof. Morris Ginsberg (London) ; (5) "Communication in Animal and Human Societies", Mr. S. A. Barnett (Glasgow) ; (6) an appraisal of the conference by Dr. J. Bronowski (director of the Coal Research Establishment) and Prof. Asa Briggs (Leeds). Further particulars may be obtained from Dr. M. P. Banton, 39 George Square, Edinburgh 8. Limited accommodation for visitors will be available in one of the University halls of residence ; early application is advised.

International Symposium on Combustion

The seventh International Symposium of the Combustion Institute will be held during August 28–September 3, under the auspices of the British Section of the Institute and the Institute of Fuel, 18 Devonshire Street, London, W.1. It is the first occasion on which the Symposium has been held outside the United States. Participants are attending from more than fifteen different countries. Dr. Bernard Lewis, president of the Combustion Institute, Dr. von Kármán, and many others will attend from the United States, and Academician N. N. Semenov will be among those from the U.S.S.R. Participants are expected to register at the Institute of Fuel on August 27. There will be a reception for those coming from overseas on that evening, given by Her Majesty's Government at Lancaster House. The opening meeting will be held on August 28 at the Royal Institution, Albemarle Street, at 10 a.m. There will also be a visit to the Laboratories of Combustion Research at the Imperial College of Science and Technology and a dinner at the Guildhall that evening, at which Lord Brabazon will be the chief guest. The rest of the proceedings will be held in Oxford, during August 29–September 3, when about a hundred papers (preprinted and circulated) will be discussed in fourteen separate sessions, only four of which will overlap.

University News : London

The following appointments in the University of London have recently been announced: Dr. D. Gabor, Mullard reader in electronics at the Imperial College of Science and Technology, to the University chair of applied electron physics at that College; Prof. L. J. Lewis, B.Sc. (Wales), former director of the University College of Ghana Institute of Education, to the University chair of education, with special reference to education in tropical areas, at the Institute of Education; Dr. J. Sutton, reader in geology, to the University chair of geology, and Dr. R. D'A. Hoyle, senior lecturer in mechanical engineering, to the University readership in mechanical engineering, both at the Imperial College of Science and Technology; Dr. W. J. H. Butterfield, to the University chair of experimental medicine at Guy's Hospital Medical School.

The title of professor in the University has been conferred on the following in respect of their posts at the Colleges and Schools indicated: Dr. R. S. Stacey (pharmacology and therapeutics in St. Thomas's Hospital Medical School); Dr. Eleanor J. Zaimis (pharmacology in the Royal Free Hospital School of Medicine).

The title of reader in the University has been conferred on the following: Mrs. J. E. Floud (sociology of education in the Institute of Education); Dr. R. J. Harrison-Church (geography in the London School of Economics and Political Science); Mr. O. R. McGregor (social institutions in Bedford College).

The title of professor emeritus has been conferred on the following, on their retirement from chairs at the Colleges and Schools indicated: Prof. W. N. Bailey (mathematics at Bedford College); Prof. K. J. Franklin (physiology at St. Bartholomew's Hospital Medical College); Prof. F. M. Haines (botany at Queen Mary College); Prof. L. Dudley Stamp (social geography at the London School of Economics and Political Science).

Dr. A. R. Fairbairn has been appointed to the General Motors Corporation of Detroit postdoctoral fellowship in flame spectroscopy, tenable at the Imperial College of Science and Technology.

Swansea

The following appointments have recently been made in the University College of Swansea: Dr. S. K. Zaremba, to be lecturer in the Department of Pure Mathematics; Dr. E. G. Brown, to be lecturer in the Department of Botany; Mr. J. D. Davies, to be lecturer in the Department of Engineering.

Announcements

The British Society of Rheology is organizing a conference on "Rheology of Road Materials" to be held at the Road Research Laboratories, Harmondsworth, on October 24. Further information can be obtained from the Honorary Secretary, 52 Tavistock Road, Edgware, Middlesex.

The second International Congress of Speleology will be held at Bari, Lecce and Salerno in Italy during October 5–12. Further information can be obtained from the secretary-general of the Congress, Prof. Franco Anelli, Castellana-Grotte, Bari, Italy.

The International Association of Allergology is holding the third International Congress of Allergology in Paris at the New Medical School during October 19–26. Further information can be obtained from the secretary, B. N. Halpern, 197 Boulevard St. Germain, Paris, 7e.

The next standard course at the Harwell Reactor School on which places are available starts on November 10, and ends on March 6, 1959. The fee for the course is £250 exclusive of accommodation. Applications will be considered from overseas as well as the United Kingdom. Forms and further information can be obtained from the Principal, Reactor School, Atomic Energy Research Establishment, Harwell, Didcot, Berkshire.

The Foundations' Fund for Research in Psychiatry announces that October 15 is the latest date for the submission of completed applications for research fellowships in psychiatry, psychology, sociology, neurophysiology, and other sciences relevant to mental health. The latest date for applications for research grants-in-aid is December 10. Further details can be obtained from the Foundations' Fund for Research in Psychiatry, 251 Edwards Street, New Haven 11, Connecticut.

The Research Fund of the Chemical Society provides grants for the assistance of research in all branches of chemistry. About £700 per annum is available for this purpose. Applications for grants will be considered in November next and should be submitted on the appropriate form not later than November 14. Applications from Fellows will receive prior consideration. Further information can be obtained from the General Secretary, The Chemical Society, Burlington House, Piccadilly, London, W.1.

Erratum. Mr. M. J. Lyons has written referring to his communication entitled "Presence of 1,2,3,4-Dibenzopyrene in Cigarette Smoke" in *Nature*, of July 19, p. 178, stating that the first sentence of paragraph 4 should read: "Small quantities of 1,2,3,4-dibenzopyrene have been detected in the exhaust products from petrol and Diesel engines".

PROGRESS IN CANCER RESEARCH

THE Seventh International Cancer Congress, organized by the International Union against Cancer, was held in London during July 6–12 under the presidency of Sir Stanford Cade. A meeting involving about 600 papers and 2,500 members is not easy to survey: as was to be expected, nothing dramatic emerged and in these circumstances it is almost impossible to judge where the most significant advances are in fact being made. Specialists in the many disciplines embraced by cancer research would all have differing ideas on this, and a short review of the proceedings must therefore be a biased one.

Hormones

O. Mülhbock (Holland) expressed the view that cancer induced by hormones is always the result of super-normal production of a growth-stimulating hormone and that hormonal deficiency never gives rise to neoplasia. Mülhbock and his co-workers have shown that breast carcinoma can be induced in mice free from the milk factor by the repeated implantation of pituitary glands from mice of the same strain. A. Lipschutz (Chile) described the occurrence of an ovarian neoplasm (luteoma) following sub-total castration. This is possibly another instance of pituitary over-stimulation. R. E. Kavetsky and his colleagues (U.S.S.R.) provided evidence that disturbance of the rhythm of activity of the pituitary gonadotropic and mammatropic hormones was a feature of high-cancer strains of mice. Another example is that described by J. Bielschowsky (New Zealand) in the case of thyroid tumours, the genesis of which is dependent on continuous over-stimulation by the pituitary thyrotropic hormone. The tumour itself may continue to be dependent on the same hormonal stimulation. This property has been utilized in treatment in man, since by administering a goitrogen the tumour can be induced to secrete thyroxin and thus become vulnerable to radioactive iodine.

One has the general impression that the relation between hormonal stimulation and cancer is being clarified rapidly and its role in the genesis of human tumours, particular of the breast, may prove important. The mechanism is still little understood, but the knowledge that certain tumours of tissues responsive to sex-hormones may still be dependent on such hormones has resulted in a significant therapeutic advance. C. Huggins (United States), who has notable achievements in this field to his credit, reviewed the treatment of cancer of the breast by surgical removal of the ovaries and the adrenal and pituitary glands. Both he and H. Shay (United States) described useful and rapid methods of inducing cancer in the breast of rats by intensive but limited oral treatment with methylcholanthrene.

Metabolism of Carcinogens

The fate of injected chemical carcinogens with its corollary, the mechanism of carcinogenesis, was a dominant topic. I. Berenblum (Israel) reviewed this subject and suggested that with the polycyclic hydrocarbons there is still no firm evidence on whether the carcinogen itself or a metabolite is the decisive factor. On the other hand, C. Heidelberger (United States) argued that carcinogenic activity is correlated directly with specific protein-binding as a first step leading eventually to the deletion of the essential enzymes regulating cell-growth. He gave evidence that the binding is in the *K* region first described by the Pullmans. A. Pullman (France) described his electronic theory and urged greater co-operation on the biological side which will be necessary to test its validity. The theory demands protein-binding with the carcinogen and not with a metabolite.

H. R. Gutmann (United States) showed that an *ortho*-hydroxyamine derivative from 2-acetylaminofluorene is capable of protein-binding in simple biochemical systems. Specific protein-binding as the primary process in carcinogenesis is an exceedingly important concept and, though not mentioned extensively at the Congress, its implications in the immunological approach to cancer were stressed by H. N. Green (Great Britain) and others.

The metabolism of the carcinogenic aromatic amines is largely linked up with studies on bladder cancer. G. M. Bonser (Great Britain) described the pioneer work by which she and her colleagues had shown that 2-naphthylamine is carcinogenic to the bladder of dog and man by virtue of its conversion to 2-amino-*l*-naphthol. The evidence that *ortho*-hydroxyamines are of importance in amine carcinogenesis in general was amplified by D. B. Clayson (Great Britain) and L. Bradshaw (Great Britain) in relation to the metabolic fate of benzidine and 4-aminodiphenyl.

E. Boyland (Great Britain) suggested that carcinogenic metabolites may be liberated in the bladder by the action on the *ortho*-amino phenol conjugates (formed in the liver) of the enzymes glucuronidase and phosphatase. He described carcinogenic *ortho*-aminophenols (for example, 3-hydroxyanthranilic acid) which are products of tryptophan metabolism and so may be endogenous carcinogens. Since urinary β-glucuronidase is inhibited by oral administration of 1 : 4-glucosaccharolactone, the possibility of preventing bladder cancer arises.

Ionizing Radiations

Interest in ionizing radiations was mainly focused on the carcinogenic hazard in man and the induction of tumours in mice. R. Doll (Great Britain) described the definite but low incidence of leukæmias induced by X-rays in man and the evidence supporting somatic mutation as the cause. A. M. Brues (United States) opposed this view, because the evidence also suggests that the risk of carcinogenesis increases disproportionately to the dosage.

One of the many interesting ways of inducing cancer by irradiation was described by P. Furth (United States) who, by irradiating the pituitary gland, produced tumours which were functional and thus induced tumours in other conditioned target organs. L. W. Law (United States) described malignant lymphomas in mice given homologous or semi-isologous bone marrow as a protection against lethal irradiation. H. S. Kaplan (United States) argued that carcinogenic agents may act indirectly since thymic leukæmias occur in the unirradiated thymus grafted into thymectomized mice subjected to prior irradiation. N. Petrov (U.S.S.R.) and his co-workers described the production of tumours in the bones of apes by the local action of radioactive minerals, an effect not obtained with carcinogenic hydrocarbons.

Viruses

Tumour viruses were widely discussed, but the outstanding interest was in the leukæmia viruses of mice. L. Gross (United States) discussed his work on the induction of leukæmia and parotid tumours with cell-free extracts of leukæmia tissues given to new-born mice. C. Friend (United States) described similar extracts rapidly inducing leukæmia in adult mice, while T. Latarjet (France) dealt with cell-free extracts —and deoxyribonucleic and ribonucleic acids derived from them—accelerating the onset of leukæmia and inducing the appearance of other tumours. These and other important contributions have great theoretical interest. Their relation to human leukæmias is doubtful, and indeed Sir Macfarlane Burnet rather disturbed the cancer virus experts by his categorical declaration on epidemiological grounds that viruses played no part in the etiology of solid tumours in man.

Immunology and Immunogenetics

There were signs of a mounting interest in the field of immunology and immunogenetics not only in the number of directly relevant papers submitted but also in the references to immunological approaches in many others. H. N. Green (Great Britain) described his immunological theory, which ascribes the neoplastic state to absence of tissue-specific immunological identity in the cell. Evidence was presented that a specific antigenic complex is formed by carcinogen binding probably with a lipo-protein complex which, possibly as a result of an immune reaction, results in the emergence of a strain of cells lacking such a complex. E. Weiler (United States) has previously found a loss of tissue-specific antigens in chemically induced tumours of the liver and kidney and, by ingenious isotopic and immune techniques, has now demonstrated their loss in the second generation of normal kidney epithelium tissue culture. The failure to induce chemical carcinogenesis, contrasted with the occurrence of malignant transformation in tissue culture, was one of the many facts presented originally in support of Green's theory. C. A. Zilber (U.S.S.R.), as well as G. P. Cunningham and his co-workers (Great Britain), indicated that an antigenic complex is formed in chemical carcinogenesis of the liver. Zilber found that this disappears, to be replaced in the tumour by a specific antigen with no carcinogen specificity. Tumour antigens are found in human and virus tumours. Antigenic change in tumours is both quantitative and qualitative.

Sir Macfarlane Burnet, in a broad survey of the biological nature of cancer, concluded that it can best be explained on a basis of somatic mutation and clone selection. The problem is to find whether these mutations are due to random action of many kinds of stimuli, deviation of some process of cellular differentiation or enforced and directed mutation by the action of specific substances. The auto-immune state is not excluded as a cause, but more experimental support is needed. G. Klein (Sweden) suggested that the evolution of the neoplastic cell towards greater autonomy is due to intercellular variation followed by selection. L. Sachs (Israel) demonstrated that though greater freedom of transplantability may involve loss of agglutinogens it always implies greater antigenicity in general, a finding which is by no means opposed to an immunological theory of loss of cytoplasmic specific antigens.

Immunological ideas are being increasingly used in experimental therapy, for example, in tagging radioiodine on to tissue-specific antibody globulin (by I. L. Spar and his co-workers in the United States).

Space does not allow of discussion of many important subjects. Naturally, the relation between smoking and cancer was a prominent topic, and half the Congress was devoted to clinical papers. These topics and the important subject of the control of cancer are of great importance, but they will be covered fully in the medical press. Chemotherapy, however, must be mentioned here, as it occupied an important part of the proceedings. Many new synthetic compounds were described, the present emphasis being away from the radiomimetic and towards the anti-metabolic compounds. Nevertheless a large amount of work still stems from the original work of A. Haddow and his colleagues on therapy with alkylating agents. Moreover, the great number of papers on nucleic acid metabolism and carcinogenesis reported at the Congress were derived largely from the original studies on the mechanism of action of such agents.

Even a long review could not be fair to every significant contribution. It is indeed very possible that among the hundreds not mentioned specifically some may have more potential importance than any cited here. For example, the work of K. Setälä and his co-workers (Finland) on the cancer-promoting activities of 'Tween 60' or of the purely physical induction of cancer by plastic films by E. T. Oppenheimer (United States) may fall within this category. The cancer scene still covers a broad canvas and the vitally important detail may not yet have been emphasized.

H. N. GREEN

BRITISH RAYON RESEARCH ASSOCIATION

OPEN DAYS

THE British Rayon Research Association held the third of its annual open days during May 7–9. The total attendance was 650–700, some 300 attending on the second day. A new technological building has been built and this houses the wool processing machinery, the work on vibration problems on spinning frames and the fluid-bed work. All the work of the Association was shown with the exception of that on fluid beds, which, as it has been moved twice in the past twelve months, was not in a suitable condition for demonstration. In order to present the fundamental work in a form which showed its relevance to problems in the textile industry, two short lectures on the work of the chemistry and physics groups were given by the senior chemist and senior physicist immediately after lunch on each day. These were well attended and well received.

Because of the disorganization caused to technological work by the vacation of the Barton Dock Road premises and the subsequent upheaval in the

Association when the additional technological building was brought into use, the different sections have been reduced in their activities for periods varying from two to three weeks to two to three months. This interruption to the work has been utilized to reconsider the machines which are required for future work and also to review the research programme. As a consequence the amount of new development which could be demonstrated was rather less than in previous years.

On the chemistry side, the work on the alkaline degradation of cellulose is being reviewed and the general picture of the mechanism of degradation has been modified to account for the presence of the large number of acidic products[1]. The study of the kinetics of the oxidation of model compounds, preparatory to a study of the oxidation of cellulose, has been continued. Even in the case of ethyl alcohol the mechanisms originally proposed have been shown not to be sufficient to account for all the kinetic results. Thus it is necessary to postulate a unimolecular decomposition of the peroxy-radical which competes with a bimolecular process; for example, in the case of ethyl alcohol the essential reactions appear to be:

$$\begin{aligned} &RO_2\cdot \rightarrow CH_3CHO + HO_2\cdot \\ &RO_2\cdot + RO_2\cdot \rightarrow 2\,CH_3CO_2H + H_2O_2 \end{aligned}$$

In the early work, anthraquinone sulphonate (Q) was used as the sensitizer, thus

$$\begin{aligned} &Q \xrightarrow{h\nu} Q^* \\ &Q^* + RH \rightarrow QH\cdot + R\cdot \\ &R\cdot + O_2 \rightarrow RO_2\cdot \end{aligned}$$

Recently hydroxyl radicals, produced by the action of ultra-violet light on hydrogen peroxide, have been used as the hydrogen atom abstractors, and it has been shown that their action is much less specific than that of excited anthraquinones. Whereas for anthraquinones the results can be accounted for by assuming abstraction of an α-hydrogen atom, it appears necessary to assume that hydroxyl radicals can abstract hydrogen atoms at other positions.

A subject of great interest to the Association is that of the fine structure in cellulosic materials. Work is still proceeding on ways of determining whether the microfibrillar structures observed could be complete or partial artefacts. During the past year or so, two approaches to the problem of determining the mechanism of formation of structure in solution-spun polymers have been started. The first method is to follow the volume changes during gelation of cellulose acetate in different solvents. The second one is to study the light-scattering of the solution.

A possible complication in interpreting the results of stress-birefringence measurements is that, in general, birefringence can be caused not only by the orientation of anisotropic polymer units but also by anisotropy in the spatial configuration of these units. Experimental departures from the simple orientation theory in solvent-swollen polymer systems have been classified under the general heading of 'Wiener effect'. Some measurements of the photo-elastic properties of swollen cross-linked rubbers have recently been made in this connexion. The effect of solvent is found to be small yet significant, but its dependence on the solvent refractive index is not of the form corresponding to the simple theory put forward by Wiener. A rigorous theoretical treatment of the transmission of light through a two-component birefringent medium has been started. It has been shown that the Lorenz-Lorentz relation is not adequate to relate birefringence to anisotropy of polarizability in stretched polymer systems and that the change in local environment when a single polymer chain is stretched can make a significant contribution to the birefringence. This effect is likely to be most important in dilute solutions where individual chains scarcely interact, but the effect may also make a small contribution to the birefringence of bulk polymers.

Certain equations relating stress and flow history, derived for polymer solutions on the basis of a network model, have been used to calculate the stress components in steady shear flow and, more recently, the deformations which occur when some or all of these components are made zero[2]. Some preliminary measurements of normal stress components in steady shear flow have been made with a newly developed cone-and-plate apparatus; a diaphragm-capacity gauge with a response time of about one second is used to measure the distribution of pressure over the plate.

Two researches on the absorption of water by crystalline polymers have been started. In the first one measurements of the moisture content of a number of textile polymers in fibre and film form have been made over a wide range of humidities and temperatures. In Urquhart's work[3] it was reported that the isotherms crossed over at high relative humidities for cotton. This work, which was started after discussion with Dr. Urquhart, does not confirm this result. An attempt will be made to correlate these measurements with the 'accessibility' of these samples of material as determined by deuterium exchange with deuterium oxide. The second research is concerned with the amount of moisture taken up by cellulose after different amounts of acid hydrolysis. In the case of cotton it has been reported that the amount of moisture absorbed first decreases with time of hydrolysis, goes through a minimum and then increases, finally levelling off and becoming independent of further hydrolysis. This result has been confirmed for cotton but, in the case of viscose, no minimum has yet been found. It may be that there is a minimum for a very small amount of hydrolysis, and this aspect is being investigated. In order to interpret these results it is necessary to make certain assumptions about the crystallite size distribution, so that the work may throw further light on both the fine structure of cellulose and the mechanism of water absorption.

Experimental work to test the fundamental theory of the geometry of yarn structures has been very fruitful. Measurements have been made of the filament path in the yarn, the packing density across the yarn section and the variation in filament twist across the yarn section. Further work on the geometry is continuing and, in the next few months, a study of the relation between the mechanical properties of the yarn and those of the constituent filaments will be started. Initial experiments using rubber as a model, which has the advantage of well-defined elastic behaviour, have already been made.

An agreement has been negotiated with a firm to produce and market most of the electronic instruments developed by the Association. The prototype electronic weft-straightener has functioned to the satisfaction of a member firm and discussions for its production are taking place. A new instrument, based on a pneumatic principle, has been developed for measuring the degree of 'raise' on raised fabrics. This instrument shows considerable promise, not only as a means of assessment, but also as a control instrument for raising machinery. The simple method of measuring warp tension in looms has been improved and instruments are undergoing tests in a number of member firms. The method may also have application in the control of tension in sizing, and suitably modified instruments are about to be evaluated in sizing machinery both at the Association and in the premises of member firms.

As mentioned earlier in this article, the work on machinery development has been restricted by internal reorganization. However, another method of controlling vibration in speed-frames has been developed and is in process of being evaluated. As for fluid beds, a full-scale single-pass bed has been constructed and this is being used for measurements of heat transfer and to assess how far laboratory data on resin-baking and dyeing are applicable under conditions approaching those in a practical machine. Apart from this, most of the development work is concentrated on designing a fluid bed suitable for dyeing fabrics constructed of hydrophobic fibres.

The number of staff is almost the same as last year. The total is 261 made up as follows: research staff, 85; laboratory and technical assistants, 75; engineering, drawing office, and maintenance staff, 60; library and administrative staff, 32; and canteen staff, 9.

DESIGN AND MANAGEMENT OF A NUCLEAR SCIENCE LABORATORY

By Prof. A. J. WOODALL, O.B.E., C. G. WILSON, Dr. A. L. JONES and D. K. THOMAS
Royal Military College of Science, Shrivenham

THE following description of a laboratory specially designed for teaching nuclear physics and chemistry at the Royal Military College of Science, Shrivenham, may be helpful to educational institutions embarking on work in this field. This laboratory has been in full use for approximately two years and it is now possible to make some assessment of the merits of the various special features incorporated in the design.

The laboratory caters for students, who range from young officers reading for science and engineering degrees to more senior officers on specialist courses. They are mostly pressed for time and more concerned with modern applications than with the history of the subject. Accordingly, modern techniques such as electronic counting are employed in experiments on properties of radioactive substances and their radiations rather than the traditional devices such as electroscopes and electrometers. The latter still occupy an honourable position in the honours degree laboratories of the College.

The subject-matter of this course has its potential hazards; this is emphasized by maintenance of a very high standard of laboratory discipline, with proper emphasis on handling precautions and health safety techniques. Maintenance of this standard is greatly assisted by the clean lines of the light airy rooms.

The laboratory was completed, inexpensively and rapidly, by the conversion of an existing 'Romney hut', the main virtue of which was a sound concrete floor, some 75 ft. by 36 ft., protected by a semi-cylindrical water-tight shell of galvanized iron. Insertion of a false ceiling and suitable vertical divisions created rooms of normal shape and voids which provide for certain services and for the ventilation system, as indicated in the typical transverse section of Fig. 1. A substantial central wall divides the building longitudinally into physics and chemistry sections. The physics side contains a nuclear physics laboratory, a gamma-radiography room, a small counting room, a photographic dark room, a small workshop and an office. The subdivision on the chemistry side, based on ascending levels of radioactivity, provides a preparation room, a monitoring room and three radiochemical laboratories in which the anticipated level of activity is graded from negligible to dangerous. This arrangement leads to a gradation of working levels with the potentially quite dangerous activation room on the chemistry side opposite the radiography room, so that both are remote from the shielded counting room and the regions in which prolonged work is performed. The radioactive sources, in suitable individual containers, are kept in massive concrete and iron safes, one in each of the two main divisions.

The rooms are separately ventilated into the roof void above the light-alloy false ceiling, which is stiffened by overhead girders and rests on the partition walls. This system minimizes inter-

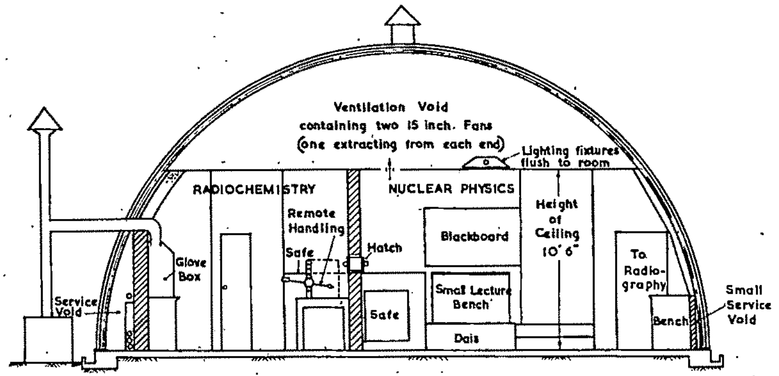

Fig. 1

change of active material between the rooms. The flow of air is governed by a pair of powerful fans and it is expelled through the original ventilating shafts on top of the building. The intake is through individual gratings to prevent one room drawing air from another. The chemistry laboratories have an additional air flow when the fume-hoods are in operation. This system could have air-filters added on the outflows if necessary. It should, however, be mentioned that current opinion inclines to make the air-flow downwards because this is assisted by the normal movement of those grosser particles which become airborne.

All exposed wall surfaces are smooth and coated with hard glossy paint, light in colour, so that splashes are easily visible. The concrete floor is completely covered with waxed polished linoleum and the joins sealed. The lighting is concealed, and all services are, whenever possible, out of sight and carried between laboratories above the false roof and inside the vertical walls. In this way surface decontamination is greatly facilitated. The main dividing wall is provided with two lead-lined hatches, so that radioactive sources can be passed from the chemistry laboratory to the physics laboratory without passing through the monitoring room.

All effluent from the monitoring room and the radiochemical laboratories passes into external delay tanks, arranged below ground-level. Such effluent is not finally discharged until the level of activity has been checked as being below the maximum agreed with the relevant authority. It should be noted that public health authorities must be consulted about all arrangements of this kind. Solid waste which might be active is put into paper bags in foot-operated medical-type waste bins. These are later sealed, and if passed for disposal, are burnt in an incinerator, remote from any habitation.

There are two neutron sources in the activation room. The larger source, an antimony–beryllium mixture with a nominal gamma-ray activity of 1 curie, is housed in a drum of paraffin wax, surrounded by a concrete cylinder built from interlocking rings with aligned holes which form vertical channels for inserting specimens for irradiation. In this way, tracer quantities of artificially radioactive materials are regularly prepared. The smaller source is of a radium–beryllium mixture, having associated gamma-activity equivalent to 20 mgm. of radium. Normally housed in a converted dustbin containing a hollow lead cylinder embedded in paraffin wax, this source is used for physical experiments involving neutrons.

Except in emergency, the monitoring room is the only means of entry to the radiochemical laboratories. Here, all staff and students check themselves for contamination before entering and when leaving the laboratories. The hand-basins have foot-operated taps, and powerful hot-air hand-dryers are used in place of towels, to reduce cross-contamination risks. All personnel wear protective overalls in all the laboratories, but, in addition, rubber gloves and canvas overshoes are worn in the radiochemical laboratories. The intake of radioactive material is so serious a hazard that eating, smoking and the like are strictly forbidden except in the office, which is adjacent to the main entrance. Since familiarity often causes research workers as well as technicians and industrial workers to become lax, and the consequences of mistakes may not show for long periods, it is essential to be rigid in enforcing this discipline, but the reasons for all rules should be fully understood and no avoidable hardship should be inflicted. For example, the hand-dryers must be very efficient so that there is no temptation to hasten operations with a surreptitious use of a handkerchief. Staff and students carry film badges and sometimes also quartz-fibre dosimeters, and a diary is maintained of individual radiation doses so recorded.

The laboratory furniture is normal, but bench tops are protected by stout water-proof waxed paper which can easily be removed after contamination. Chemical experiments are 'contained' in stainless steel trays lined with tissue paper. Normal chemical manipulation is drastically modified, there being no sniffing and tasting, while wash-bottles are replaced by plastic squeeze-bottles and pipettes are piston-operated. The preparation of sources which are powerful alpha- or beta-emitters is carried out in a glove-box, having rubber gloves sealed into apertures in the 'Perspex' windows: strong gamma-emitters are handled behind an appropriate shielding wall of interlocking lead bricks by remote handling gear. The weight of the walls is taken by the reinforced concrete bench which, incidentally, shields the lower part of the body.

Most of the apparatus on the physics side comprises various forms of radiation detector and counting equipment. The standard counting unit consists of a Geiger–Müller tube housed in a lead 'castle' and connected to a dekatron scaler by a small pre-amplifier and delay circuit. The voltage supply for the Geiger tubes is provided by power packs, each capable of feeding several units. In addition, three rate-meters are available for the direct measurement of counting rates, using end-window or liquid detectors. A pen recorder in conjunction with a rate-meter enables the decay curve of some isotopes to be traced directly. Battery-operated radiation monitors and Radiac equipment are used in simple experiments, apart from serving as laboratory monitors and survey meters. More specialized equipment includes two scintillation counters (one is incorporated in a single-channel gamma-ray spectrometer); two vibrating-reed electrometers, used for alpha-ray range determination and for ionization current measurements, etc.; and a home-made, thin-lens type, beta-ray spectrometer.

Weak radioactive sources (micro-curies) are prepared by evaporation from nickel planchettes of diluted radioactive solutions obtained from the Radiochemical Centre, Amersham. Infra-red lamps are used for this operation to avoid possible spray. The planchettes are mounted on thin 'Perspex' sheets designed to fit into a lead castle. More active sources (milli-curies) as wire or foil are obtained from Harwell. For gamma-radiography, the main source is of iridium-192 of several curies strength, used in a gamma-ray 'bomb' container. When the stronger sources are used in the exposed state in an experiment, lead brick shielding is used to ensure a reasonably low background throughout the laboratory. It has been found possible to cast suitable lead bricks very cheaply in the college workshops.

The experiments carried out in the physics section include the characteristics of the absorption of alpha-, beta- and gamma-rays; the calibration of dosimeters and of film badges; the survey of contaminated ground; the determination of beta- and gamma-ray spectra; the slow neutron flux obtained from a neutron source immersed in water; the characteristics of Geiger and scintillation counters; the decay curves of irradiated silver; the use of nuclear emulsions; and the production of gamma-radiographs. On the chemistry side, the experiments include the production and isolation of radioactive iodine; slow-neutron activation analyses; isotopic dilution analyses; separation using exchange resins and the solubility of lead sulphate. The experiment schedules are modified to cater for the differing academic levels of students using the laboratory.

The laboratory caters for a maximum of thirty students at a time, of whom about twenty would be on the physical side and the rest doing chemical experiments. This represents a fairly high concentration of personnel in the working space, and constant vigilance is required to prevent excess local background, especially when sources are moved. Writing records of experiments is then usually carried out in a neighbouring building.

The capital cost of conversion, including benching, ventilation and drainage, for a laboratory on this scale, is likely to be in the region of £5,000; a brand-new building would cost much more and take longer to construct. Equipment at the standard adopted for this laboratory is comparable in cost. It is felt that the high initial cost of carefully chosen commercial apparatus has been fully justified in the sequel by the excellent service it has given and by the low maintenance costs.

We wish to record our indebtedness to those members of the Atomic Energy Research Establishment and the Atomic Weapons Research Establishment, who were consulted during the planning stage, for their valuable advice and to the Garrison Engineer at Shrivenham and his staff for their co-operation and professional skill. To those who contemplate similar ventures we would warmly recommend a close study of laboratories of high standard. There are many points of detail which cannot be included in an account of this kind, but which make a difference to smooth and efficient running of the laboratories and reduce the risk of accident. The close co-operation of physicist and chemist in the design and operation of the laboratory has played a notable part in promoting its efficiency and its usefulness to the students, who gain a more balanced picture of the subject in this way.

THE ELECTRICAL RESEARCH ASSOCIATION

THE Electrical Research Association has recently completed its first year of work, under the direction of Dr. H. G. Taylor, at the new laboratories at Leatherhead. Changes and developments are reflected in some measure in the form as well as in the content of the annual report for 1957* which was presented at the annual general meeting held on May 7.

It is with regret that we record the death, on the day of the meeting, of Mr. F. H. Bramwell, chairman of the Council of the Association, over whose signature the report of the Council appears in the annual report.

In the matter of framing research policy it is noteworthy that the Council now has the benefit of drawing upon the knowledge and experience of an Advisory Research Board, the constitution of which is given in the report under the list of committees and panels. On the administrative side a new post of research manager has been established and is occupied by Mr. L. Gosland, who was formerly head of the switchgear department.

In order to form some assessment of the extent to which the Association's research effort is co-ordinated with the interests of members, a questionnaire was issued during the year inviting opinion as to the application of the Association's research funds. The results were weighted in relation to the value of members' subscriptions and a final percentage analysis prepared. This analysis is found to be in reasonably good correlation with the relative scale of the Association's activity in its various fields, and although it does not show a pressing demand for work in any field in which the Association is not at present engaged, there is a significant emphasis on the subject of the nuclear irradiation of dielectrics, cathodic protection, climate proofing, nuclear power and semi-conductors. The results of this questionnaire provide very useful guidance for future policy.

Mention is made of the difficulties which have been experienced in filling vacancies on the senior scientific staff and of the efforts which are being made to interest young university graduates in engineering and in physics in the work of the Association. The total number of staff employed by the Association at the end of the year under review was 348.

In the field of insulation, which constitutes one of the major areas of the Association's work, a result of considerable practical significance has been obtained in the demonstration of the importance of moisture content in controlling the discharge inception-level of cellulose. Confirmation has also been obtained, in the case of one of the new high-density polyethylenes, of the recently propounded electro-mechanical theory of breakdown.

It is interesting to note that it has been found desirable to initiate a fundamental study of the mechanism of oxidation of hydrocarbon oils. This programme is being carried out in three university departments. The need to supplement the great body of existing knowledge of the behaviour of hydrocarbon oils as insulants for electrical apparatus arises from the urge to raise the working temperature of transformers.

In another important branch of the Association's work, that of circuit breakers and circuit-breaking phenomena, progress is reported in the breaking of both low and high currents in vacuum and, in relation to the arc itself, theoretical predictions of high arc-core temperatures (35,000° K.) have been confirmed by spectroscopic measurements.

Two interesting full-scale experiments relating to electric power systems are reported. These were carried out in collaboration with the Central Electricity Authority. The stability of a large national electricity supply system under conditions of overload or of transient disturbance is naturally a matter of importance and studies of system stability are made using network models known as network analysers. The validity of the results of such studies is in large measure dependent upon the correctness of the values of the system constants used in setting up the model system, and these have often to be based on indirect computation. There is therefore great interest in the carrying out of stability tests on actual power systems whenever such full-scale tests can be arranged. The first large-scale experiments on system stability to be made in Britain were carried out during a Bank Holiday week-end at the Cliff Quay Generating Station of the Central Electricity Authority. The performance of the system was predicted on three models, the network analysers of the Association and of the Associated Electrical Industries organization together with the 'Micro Réseau' of Electricité de France. The results of these tests will be communicated in a group of papers to be read before the Institution of Electrical Engineers. It is, however, stated in the report that the behaviour of the system was in general agreement with prediction.

---

* Electrical Research Association. Thirty-seventh Annual Report for the year ended 31st December, 1957. Pp. 119+8 plates. (Leatherhead: Electrical Research Association, 1958.)

The second experiment concerned the strength of the foundations of transmission towers. The opportunity to make tests on a series of erected towers occurred as a result of the decision of the South Eastern Electricity Board to discontinue the use of a section of 33 kV. line in the Guildford area. Mechanical loading tests were carried out on the towers with the view of determining the strength of their foundations. The report on these tests has not yet been issued, but it is stated that the strength of the foundations was considerably less than had been expected.

The Association's work on intrinsically safe circuits for measurement and control in an atmosphere of explosive gases has included acetylene and ethylene. As a result of this, ethylene has been included in the list of gases covered by the appropriate British Safety Standard, and certification is now available for apparatus to be used in an ethylene atmosphere.

An attractive new feature of the annual report is the inclusion of a group of photographs illustrating aspects of the research work. One of these is a reproduction of a thunderstorm distribution map for 1957 for England, Wales and Scotland. The accumulation by the Association of data concerning lightning flashes is proving to be of increasing value. Towards the end of the report is given a list of universities, colleges, Government establishments and national authorities in which the extramural research of the Association is being carried on, in each case stating the subject of the research programme and names of those responsible for the work.

J. GREIG

GENETICS OF BETA-GLOBULIN POLYMORPHISM IN BRITISH CATTLE

By G. C. ASHTON

The Animal Health Trust, Farm Livestock Research Station, Stock, Essex

IN a preliminary communication five serum β-globulin phenotypes of cattle, identified by starch gel electrophoresis, were described[1]. A sixth phenotype has now been found, and as a result it is possible to propose a genetic mechanism for the system.

The six phenotypes are shown in Fig. 1 together with the postulated genotypes. The mating data and symmetrical appearance of the phenotypes suggested that a three-allele system (genes β^A, β^D, and β^E) with no dominance is operative. The homozygotes type I (β^A/β^A), type IV (β^D/β^D), and type VI (β^E/β^E) are individually recognizable. The heterozygotes are also recognizable as such; thus type II (β^A/β^D) is clearly a composite of types I and IV, type III (β^D/β^E) a composite of types IV and VI, and type V (β^A/β^E) a composite of types I and IV. Equal mixtures of the appropriate homozygous β-globulin sera are indistinguishable qualitatively from genuine samples of heterozygous serum when run side by side. Each of the phenotypes I–VI is thus a single genotype, and it is therefore appropriate to discard the numerical terminology and name each phenotype by its genotype. The expected distribution of phenotypes (genotypes) is shown in Table 1, while pooled mating data for a number of breeds are shown in Table 2. The expected and observed results agree when tested by the χ^2 test.

In the preliminary communication[1] only five phenotypes had been recognized, and to fit the mating data reported at that time it was necessary to postulate a series of linked genes. However, with the finding of the sixth phenotype (β^{EE}) the genetic mechanism became clear and it was apparent that five of the 150 matings previously reported[1] (two I × IV → I; one I × IV → IV; one III × V → I; one III × V → IV) were not possible on the 3-allele

No matings between β^{EE} and β^{AD}, β^{DE}, β^{AE} or β^{EE} have been observed

theory indicated by the sixth phenotype. These mating results were re-investigated and in each case proved to be false after critical examination. In this connexion Rendel[2] found that the stated parentage was in error in about 8 per cent of sire-dam-offspring families blood-grouped in Sweden. It is thus probable that the β-globulin system will be of assistance in checking parentage.

The five phenotypes previously reported[1] were found independently by Smithies and Hickman[3]; on the basis of 71 mating results within two herds they postulated a three-gene theory for cattle β-globulins also, although their interpretation of the expression of each gene has proved to be incorrect.

In order to establish reliable gene frequency data for each breed of cattle it is necessary to examine a representative cross-section of each breed. It is difficult to get a truly random sample by examining cattle indiscriminantly, due to the preponderance of herds using one or two bulls only. However, with the advent of artificial insemination representative groups of pedigree bulls drawn from many sources have been established, and these bulls each serve many hundreds of cows and heifers every year.

Table 3 shows the distribution of phenotypes in bulls standing at Milk Marketing Board cattle-breeding centres compared with bulls standing at other centres.

Gene frequencies for each breed from both groups of centres are shown in Table 4. The results were calculated from the relationships, $A = (2\beta^{AA} + \beta^{AD} + \beta^{AE})/2N$, $D = (\beta^{AD} + \beta^{DE} + 2\beta^{DD})/2N$, and $E = (\beta^{DE} + \beta^{AE} + 2\beta^{EE})/2N$, where β^{AA}, β^{AD}, etc. are the numbers of animals of this phenotype found for any given breed and N is the total number of animals, and where A, D and E are the frequencies of genes β^{A}, β^{D} and β^{E} respectively. The standard errors of the gene frequency estimates were calculated from the expression $\sqrt{1/2N.\ [g(1-g)]}$, where g is gene frequency.

It will be seen that the gene frequencies calculated from both groups of breeding centres are consistent for each breed, within the standard errors found. The gene frequencies found for each breed, therefore, are probably fairly representative for that breed in Britain.

It is evident that the frequency of β^{E} is greater in those breeds originating in the climatically more severe parts of the British Isles. Thus β^{E} is absent in Jersey, Guernsey, Devon and South Devon cattle, confined mainly to the south and south-west of England, while it is most frequent in cattle of Scottish origin. Furthermore, the frequency of this gene within the Ayrshire breed is associated with the location of the herd. In a herd using artificial insemination selected at random in Essex the frequency of β^{E} was 0·118 ± 0·025 (80 animals), which is in agreement with the expected value (cf. Table 3). In a comparable herd (67 animals) in Aberdeenshire, on the other hand, the frequency of β^{E} was 0·261 ± 0·037, while Hickman and Smithies[3] found a frequency of 0·279 ± 0·049 in an Ontario Ayrshire herd (42 animals). These results suggest that β-globulin polymorphism in cattle may be concerned with climate

Table 3. DISTRIBUTION OF PHENOTYPES OF 808 PEDIGREE BULLS AT CATTLE-BREEDING CENTRES

tolerance. It is significant that the average heat adaptability coefficients of some breeds of cattle, quoted by Findlay[4], are in inverse order to the β^E frequencies; for example, Jersey adaptability coefficient 79, β^E nil; Hereford 73, β^E 0·013; Aberdeen Angus 59, β^E 0·115. In view of the high adaptability coefficient (89) of Brahman cattle, it will be worth while investigating the β-globulins of these animals.

It is noteworthy that recently described β-globulin polymorphism in humans sharply distinguishes the black and white races[5]. Polymorphism involving the β-globulins has also been found in sheep[6], goats, horses and rhesus monkeys[7]. This may prove to be one mechanism, therefore, by which a species is able to adapt itself to both temperate and tropical climates.

I gratefully acknowledge the co-operation of the veterinary officers and managers of the various artificial insemination centres in sending samples of bull blood, and of Mr. W. Thomson, of the Duthie Experimental Stock Farm, Aberdeenshire, for supplying blood samples from Ayrshire cattle. I am indebted to Mr. J. C. Gower of Rothamsted for help with the calculation of gene frequencies and errors.

GROUP-TRANSLOCATION: A CONSEQUENCE OF ENZYME-CATALYSED GROUP-TRANSFER

By Dr. PETER MITCHELL and Dr. JENNIFER MOYLE
Department of Zoology, University of Edinburgh

RECENT research on bacterial permeability[1], metabolism[1,2] and adaptation[2] has shown that the kinetics of the passage of metabolites through the plasma-membrane of bacteria closely resembles enzyme kinetics; and it has been inferred that certain protein components of the plasma-membrane may act as highly specific conductors of membrane-transport. We have suggested that normal enzyme systems are the conductors of membrane-transport and that metabolic energy is generally converted to osmotic work by the formation and opening of covalent links between enzymes or co-enzymes in the membrane and the transported 'molecules' that are carried as chemical groups exactly as in enzyme-catalysed group-transfer reactions[1,3]. This view has been supported by the observation that the plasma-membrane of certain bacteria is partly constituted of normal enzymes and carriers[4]. On the other hand, using a less direct but very elegant approach to the problem, Cohen and Monod have recently adopted a view that they attribute to Danielli[5]. They suppose that "the rapid permeation of hydrophilic organic compounds into cells is ensured by stereospecific and functionally specialized protein components of the plasma-membrane". They have introduced the word 'permease' to distinguish these supposedly functionally specialized catalysts of facilitated diffusion and also of active transport from metabolic enzymes, and have thus retained the old problem of the mechanism of energy coupling between metabolism and the catalysts of the osmotic processes.

The object of the present communication is to amplify our own conception of the connexion between normal enzyme catalysis and the movement of chemical groups in space[3], and to demonstrate again in a more general context that the active transport of metabolites can be adequately explained in orthodox biochemical terms.

The recent developments on the border between enzyme kinetics and metabolic enzymology have led to a spatially more realistic description of enzyme catalysis than was generally accepted before, by focusing attention upon the enzymic transfer of chemical groups and by considering the enzyme as a reactant in group-transfer reactions[1,7]. For example[7], certain phosphokinases (E) are believed to mediate in the transfer of phosphoryl between adenosine triphosphate (ATP) and the substrate (S) being phosphorylated (forming EP) as follows:

$$\mathrm{ATP} + \mathrm{E} \rightleftharpoons \mathrm{ADP} + \mathrm{EP}$$
$$\mathrm{EP} + \mathrm{S} \rightleftharpoons \mathrm{E} + \mathrm{SP}$$

Evidently there must be a spatial movement (translocation) of phosphoryl relative to adenosine diphosphate and the substrate in relation to the enzyme molecule as represented in Fig. 1, supposing the reaction to be on the enzyme 'surface', or as in Fig. 2 supposing the reaction to occur in a cleft in the molecule—the movement of phosphoryl from adenosine diphosphate to the substrate possibly involving thermal distortion of the enzyme itself as suggested previously[3]. The group-translocation accompanying group-transfer illustrated by this example is, we suggest, a phenomenon general to many enzyme-catalysed group-transfer reactions, including hydrogen and electron transfer. The translocation implicit in the transfer process would, of course, have no macroscopic effect in a homogeneous system and might, under these conditions, be passed over as unimportant. If the system is not

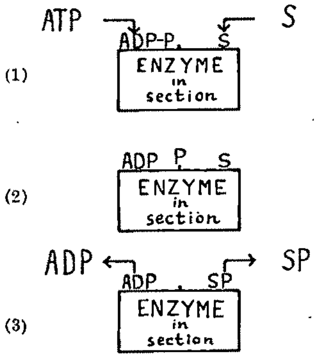

Fig. 1

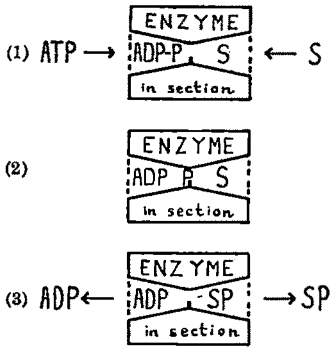

Fig. 2

homogeneous, however, group-translocation may have a biochemically important macroscopic consequence.

It is possible to envisage both a macroscopic and a microscopic type of inhomogeneity that may cause group-translocation to show macroscopically. In the macroscopic type, the enzyme molecules must be orientated in a membrane in such a way that certain components react with the active centre from one side (or from both sides) while one or more other components react only from the other side. The essential consequence of this state of affairs would be that a chemical group must pass across the membrane during the enzyme-catalysed reaction. The enzyme as depicted in Fig. 2 could give rise to the effect that we are describing simply by being imbedded in an inert osmotic barrier with the cleft connecting the phases on either side; and even the more usual representation (Fig. 1) would give rise to the same effect if the enzyme molecules were orientated so that the part of the osmotic barrier lying close to the active centre formed a cleft connecting the phases on either side like that envisaged in the enzyme itself in Fig. 2. In this way, membrane-transport and metabolism can be integral consequences of the same enzyme-catalysed process.

The microscopic type of inhomogeneity that may cause group-translocation to be macroscopically significant requires the participation of a second enzyme that can catalyse a change in the product of the first enzyme reaction. In this case we can visualize the inhomogeneity as a pairing of the different enzyme molecules so that a product of the first enzyme reaction diffuses to the active centre of the second enzyme faster than it escapes into the neighbouring region of the medium. The possible consequences of this type of inhomogeneity are of more than theoretical interest, because the grouping of enzymes and carriers into double- or many-functional particles within which the reactions are closely integrated is well known[8].

The highly organized particle and membrane systems of most animal and plant cells recently discovered have presented new problems of spatial metabolic organization that have taxed the imagination of biochemists[8]. We suggest that the concept of group-translocation may provide the basis for a new but essentially orthodox biochemical approach to these problems. A more detailed account of group-translocation will be published in due course[9].

We would like to thank the Scottish Hospital Endowments Research Trust for personal grants in support of our work.

OXIDATIVE METABOLISM OF POLYCYCLIC HYDROCARBONS BY SOIL PSEUDOMONADS

By H. N. FERNLEY and Prof. W. C. EVANS

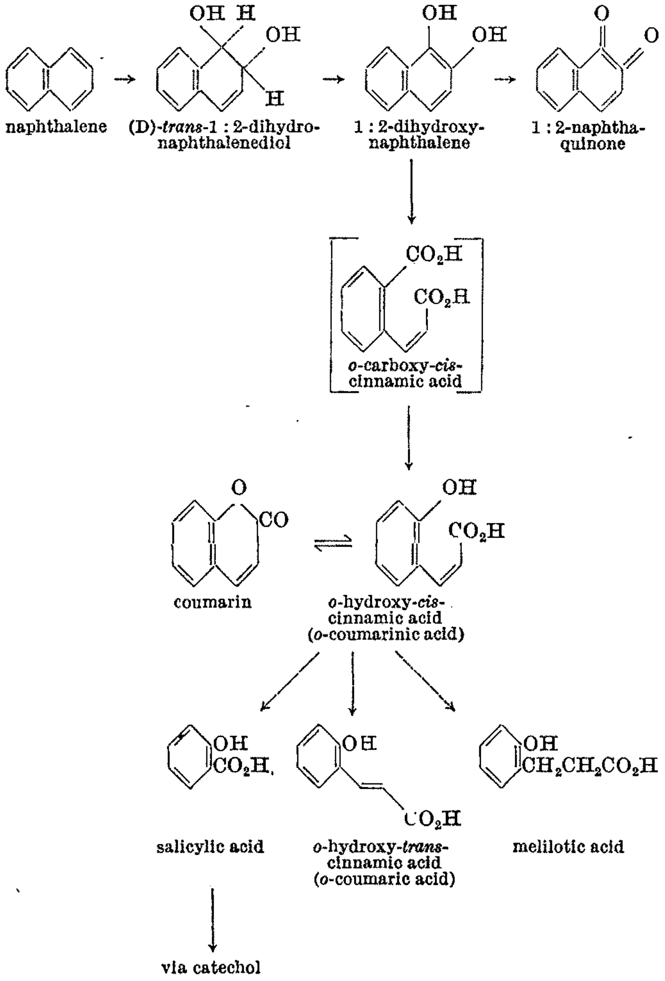
Department of Agricultural Chemistry, School of Agriculture, University College of North Wales, Bangor

THE intermediary pathways through which monocyclic aromatic compounds are metabolized by soil bacteria have been summarized by Evans, Smith, Linstead and Elvidge[1]. It has been known since the work of Tausson[2] that several polycyclic hydrocarbons, for example naphthalene, anthracene and phenanthrene, also serve as substrates for certain soil organisms and are metabolized completely. A knowledge of the precise method of biochemical attack on these polynuclear hydrocarbons may help towards understanding the microbial oxidation of naturally occurring condensed ring systems.

In naphthalene cultures of a *Pseudomonad* strain, Strawinski and Stone[3] identified salicylic acid; Walker and Wiltshire[4], in addition, isolated D-*trans*-1 : 2-dihydro-1 : 2-dihydroxynaphthalene, and showed by the sequential induction technique that both were intermediates in the metabolism of this hydrocarbon. The latter workers also studied the breakdown of 1-chloronaphthalene[5] by a suitable organism, identifying 8-chloro-1 : 2-dihydro-1 : 2-dihydroxynaphthalene and 3-chlorosalicylic acid as intermediates. These results made it very probable that C-5 in 1-chloronaphthalene became the carboxyl-C of 3-chlorosalicylic acid. Murphy and Stone[6] found that 1 : 2-naphthaquinone accumulated, eventually in toxic amounts, in naphthalene cultures of their strain of *Pseudomonas*.

Recently, Rogoff and Wender[7,8] have shown that phenanthrene and anthracene are also metabolized through end-ring attack, by members of the genus *Pseudomonas*. Thus, from phenanthrene cultures

Scheme 1. SUGGESTED PATHWAY FOR THE END-RING ATTACK ON NAPHTHALENE BY SOIL *Pseudomonads*



naphthalene
(D)-*trans*-1 : 2-dihydronaphthalenediol

salicylic acid
o-hydroxy-*trans*-cinnamic acid (*o*-coumaric acid)
melilotic acid
via catechol

they isolated 1-hydroxy-2-naphthoic acid, while anthracene cultures afforded 3-hydroxy-2-naphthoic acid, as intermediates. Both these acids were afterwards metabolized through salicylic acid into the catechol pathway, as shown by sequential induction experiments.

The ultimate product of end-ring fission in the microbial metabolism of polycyclic hydrocarbons is therefore salicylic acid or an analogue. Intermediate stages in the breakdown of the end-ring have not, however, been ascertained.

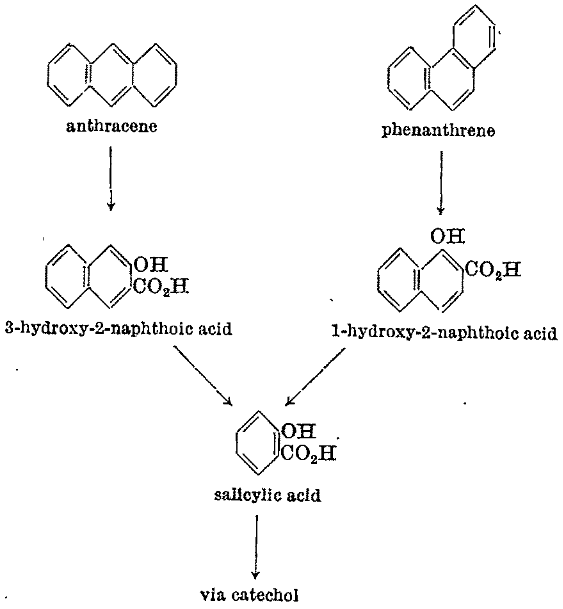
Cultures of a *Pseudomonad* strain isolated from conifer litter, growing ærobically in a simple mineral salts medium[9] with naphthalene as sole substrate, gave coumarin from the acid-ether fraction, detected by smell, and identified by chromatography, absorption spectrum ($\lambda_{max.}$, 277 mμ in water), and mixed melting-point with an authentic sample. It would appear that *o*-hydroxy-*cis*-cinnamate is the actual metabolite present in culture and not coumarin itself, since this would have occurred in the neutral-ether fraction, which was not the case. These cultures also contained, at various times, detectable amounts of *o*-hydroxy-*trans*-cinnamic acid (*o*-coumaric acid), *o*-hydroxyphenylpropionic acid (melilotic acid), and salicylic acid, as shown by their chromatographic separation, fluorescence, absorption spectra, and various colour reactions. Some minor chromatographic spots remain unidentified.

Bacterial cells grown on naphthalene were sequentially induced to oxidize *trans*-1 : 2-dihydro-1 : 2-dihydroxynaphthalene and salicylic acid in accordance with the results of previous workers[4,5], and also to 1 : 2-dihydroxynaphthalene. Coumarin, *o*-coumaric and melilotic acids regularly gave oxygen-uptakes considerably in excess of the control cells, but the rates were rather slower than those of the former substrates. Negative results were obtained with two synthetic *o*-carboxycinnamic acids (m.p. 175° C. and 197–205° C. respectively[10,11]), *o*-carboxyphenylpropionic acid, phthalide acetic acid, *o*-carboxybenzoylacetic acid, and phthalic acid.

A crude cell-free extract prepared from naphthalene-grown cells rapidly oxidized pure 1 : 2-dihydroxynaphthalene, with the consumption of approximately 3 atoms of oxygen, and the liberation of 1 mole of carbon dioxide per mole of substrate. Coumarin was isolated as the major product of this enzyme action, on acidification and ether extraction. By analogy with previous work in this field[1], the immediate product of ring fission is presumably *o*-carboxy-*cis*-cinnamate, but we have no evidence, as yet, of its formation. Neither of the synthetic *o*-carboxycinnamates is acted upon by this crude enzyme preparation, but this may be because they are both varieties of the *trans*-isomer, whereas the bacterial enzyme would be expected to be stereo-specific towards the *cis*-form[12]. The production of *o*-hydroxy-*cis*-cinnamate (isolated as coumarin) is explained by an oxidative decarboxylation of the presumed labile *o*-carboxy-*cis*-cinnamate; the molar gaseous exchange is in agreement with this view.

On the basis of these results, the oxidative

Scheme 2. SUGGESTED PATHWAY FOR THE DISSIMILATION OF ANTHRACENE AND PHENANTHRENE BY SOIL *Pseudomonads* (ref. 8)



microbial metabolism of the end-ring of naphthalene is suggested as proceeding according to the pathway shown in Scheme 1. Naphthalene is first oxidized to the D-*trans*-dihydronaphthalenediol, which is normally dehydrogenated to 1 : 2-dihydroxynaphthalene prior to ring fission, but in certain circumstances (depending on the organism and cultural conditions) further oxidation to the toxic 1 : 2-naphthaquinone occurs. Ring cleavage of 1 : 2-dihydroxynaphthalene is assumed to proceed through *o*-carboxy-*cis*-cinnamate, which is oxidatively decarboxylated to *o*-hydroxy-*cis*-cinnamate. The other related products identified in naphthalene cultures could arise by well-known biochemical reactions from this key intermediate, for example : (*a*) by β-oxidation salicylic acid, afterwards to be metabolized via catechol[13], (*b*) isomerization and reduction, *o*-coumaric and melilotic acids, afterwards to be metabolized by an unknown route.

Our present information as to the pathway of oxidative microbial metabolism of anthracene and phenanthrene is shown in Scheme 2 after Rogoff and Wender[8]. End-ring attack may occur in an analogous manner to that of naphthalene, through the cleavage of 1 : 2-dihydroxyanthracene, and 3 : 4-dihydroxyphenanthrene respectively.

It will be a future task to elucidate the enzymology of this metabolic sequence, and to explore its relevance to the breakdown of polycyclic compounds in general.

ETCHING OF RADIATION DAMAGE IN LITHIUM FLUORIDE

By Dr. D. A. YOUNG
Chemistry Division, Atomic Energy Research Establishment, Harwell

FROM experiments on the coloration induced in potassium chloride by fission fragments allowed to recoil into the crystal, it was proposed[1] that the unannealed recoil tracks consist of individual and aggregated lattice defects with trapped positive holes and electrons. During optical bleaching of the *F*-band, the *F*- and electron-excess centres aggregate to form *R'*-centres along the core of the damage produced by the recoiling fragment, and it was suggested that in respect of chemical properties, that is, precipitation, the recoil track is similar to a heavily jogged dislocation.

The damage produced in ionic crystals by recoiling fission fragments from an external source has now been examined by another technique. It was argued that the thermodynamic potential of the crystal should be increased around those regions of the surface at which the fission fragments are injected, and that this should manifest itself in an enhanced rate of dissolution with respect to the undamaged crystal surface. That is to say, etch-pits should be formed as at dislocations. Accordingly, single crystals of lithium fluoride were cleaved along the {100} plane and fission fragments from a U_3O_8-film 1 mm. distant allowed to enter a portion of the crystal surface at room temperature. The crystals were then etched in the mixture of concentrated hydrofluoric acid (1 part) and glacial acetic acid (1 part) saturated with ferric fluoride, which was recommended for the purpose by Gilman and Johnstone[2]. After etching without agitation for between 1 and 42 min. at 12° C., the crystals were washed in absolute alcohol and dry ether, dried in a warm air current and photographed under oblique illumination in a Vickers projection microscope.

The crystal illustrated in Figs. 1–4 was exposed to a total thermal neutron dose of 3×10^{10} cm.$^{-2}$, which corresponds to a fission fragment dose of 1×10^7 recoils per cm.^{2} of crystal surface. Etching times and magnifications are given in the legends. A general view of the boundary of the bombarded region is shown in Fig. 1 and an expanded view of part of the boundary is shown in Fig. 2 at an earlier stage of the etching. From this latter photograph it may be calculated that the etch-pit density is 8–9 × 10^6 cm.$^{-2}$, from which it appears that one etch-pit is formed for each fission fragment after allowance is

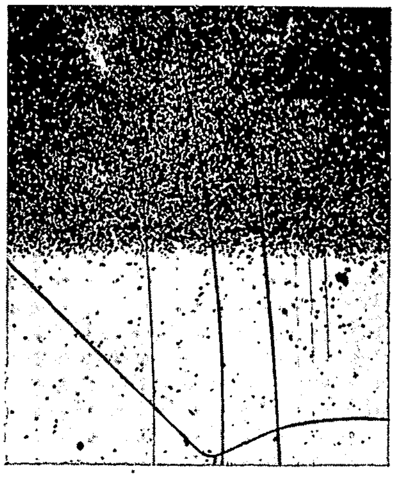

Fig. 1. General view of the boundary of the bombarded region. 32 min. etch. (× 60)

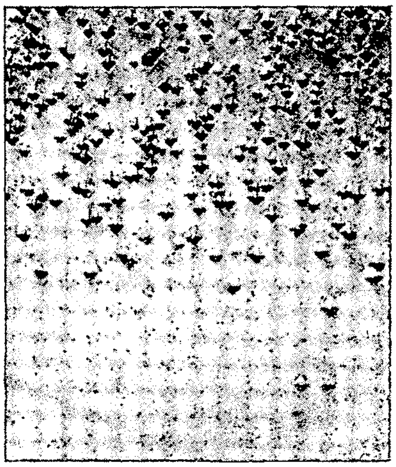

Fig. 2. Expanded view of a section of the boundary of the bombarded region. 8 min. etch. (× 640)

made for overlap. No new phenomena are introduced as the density of fission fragments is increased to 10^{12} cm.$^{-2}$, and at no stage has any effect of the ^{6}Li(n,α)^{3}H reaction been observed, though even in the photographed crystal some 10^8 n,α events cm.$^{-2}$ must have occurred within recoil range of the surface. Even heavily bombarded surfaces (10^{12} fission fragments per cm.^{2}) reveal no sputtering or surface structure before etching. So far as etching is concerned, the damage appears to anneal out completely between 450 and 500° C., as suggested by the results of Smallman and Willis[3]. There is no evidence of polygonization during gentler annealing treatments.

When small ($< 1\mu$), the etch pits grow more rapidly than when they are large, and commonly exhibit central depressions, as shown in the electron micrograph, Fig. 3*a*. Other electron micrographs, Figs. 3*b* and *c*, clearly show that the walls of the etch pits consist of finely spaced terraces and are not planar, the walls becoming steeper towards the centre of the pit. As the pits grow larger, the rate of linear growth is reduced. Two types of growth appear to be possible. Some pits remain fairly shallow over most of their area, but retain a central depression, whereas others, in the minority, grow as deep regular square pyramids throughout their lives. Examples of both types of growth are shown in Figs. 2 and 4. We therefore propose that in the case of etching recoil tracks, the initial process is a rapid dissolution of highly disordered material at the centre of the track. This rapid dissolution permits the development of crystal faces which are not necessarily those of lowest surface free energy though they have the correct symmetry for the {100} face. Rapid dissolution continues until the etch pit exceeds the boundary of the track, when the normal crystal structure determines the rate of dissolution and the angles at which the etch pit faces meet the surface. It is also of general interest to note that damage which may be etched is caused even by fission fragments at the commencement of their tracks. This means that we cannot assume, as is often done for energetic charged particles, that simple ionization predominates at the beginning of the track. Lattice displacements, albeit by mutual repulsion of highly ionized constituents, are important at the beginning of a fission fragment track.

SPECIAL PRE-PUBLICATION ANNOUNCEMENT

The United Nations announces the publication in English of the complete

PROCEEDINGS OF THE SECOND UNITED NATIONS INTERNATIONAL CONFERENCE ON THE PEACEFUL USES OF ATOMIC ENERGY (Geneva, September 1st to 13th, 1958).

More than 2,200 papers (double the number presented at the 1955 Conference), covering all aspects of the Peaceful Uses of Atomic Energy, will be presented at the Conference in which approximately 70 countries will participate and discuss their latest achievements, both experimental and practical.

The main subjects of the Conference are listed below :

Basic physics
Basic chemistry
Biology and medicine
Use of nuclear energy for purposes other than generation of electricity
Thermonuclear developments
Possibility of controlled fusion
Raw materials
Production of nuclear materials
Research and power reactors
Reactor technology
Production and uses of isotopes
Training in nuclear sciences

The English edition is expected to consist of 34 volumes (approximately 500 pages each) which will become available beginning December, 1958 ; publication is expected to be completed by June, 1959.

A special pre-publication price of £155 (or equivalent in other currencies) for the complete set is now available, and orders will be accepted on this basis until November 30th, 1958. The regular price for the full set will approximate £182.

Abridged editions in French and Spanish are planned for simultaneous publication. They will consist mainly of the papers presented orally at the Conference (approximately 500), the papers submitted in the language of the edition, and a selection of other papers. These editions are expected to be in 15 volumes, and a pre-publication price is available (up to November 30th, 1958) of £68 or equivalent in other currencies:

The Man-made Fibres Industry

R. ROBSON

AUTHOR OF *The Cotton Industry in Britain*

The first book to tell of the development and structure of the industry, its economic and scientific basis, in England and overseas. 'Compactly written . . . to the point and right up-to-date. It can be thoroughly recommended to anyone who is confused by the complexity of the situation within the man-made fibre industry in which new fibres are emerging daily.'—*Skinner's Silk and Rayon Record.* 21*s*

Looking at Chromosomes

JOHN MCLEISH and BRIAN SNOAD

The aim of this book is to demonstrate, by means of a continuous series of photographs and illustrations, how cells and the hereditary substances they contain behave during the growth of a living organism, how the cells which function in reproduction come to be formed and, finally, how the hereditary substances are passed on from parents to offspring. Of great value to students with some knowledge of biology.

ENDECOTTS
TEST SIEVES

Inside Story

No crevices to trap particles; frame and wire cloth are joined as one.

Guaranteed Accurate
Manufactured under licence from the British Standards Institution.

Mechanical Sieving is ideal with Endecotts Sieves—several simultaneous tests are possible with intermediate receiving pans.

British, U.S. Standards and Tyler Equivalents are readily available, many other international standards also supplied.

"Endrock" Test Sieve Shaker saves valuable time and effort of skilled personnel; similar to manual motion but is more consistent, having a regular mechanical action—a time switch controls the length of time for tests.

We operate a **Recovering Service**—if sieving is important to your business, ring or write for literature—or for any advice you require—we'll be glad to help.

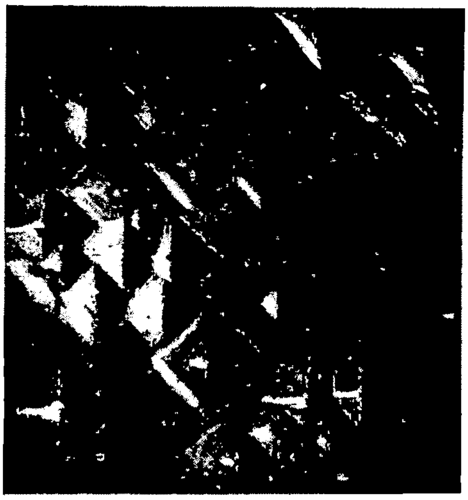

Fig. 4. Optical micrograph of the bombarded surface after soaking for 42 min. in the unstirred etch solution. (× 1,260)

If the above argument is qualitatively correct, the region of substantial lattice damage around the fission recoil track may reach a diameter of about 5000 A. in lithium fluoride. We conclude from the absence of polygonization and the low energy input, which is insufficient to raise the temperature of the surface layers even by 0·1° C., that classical dislocations are not formed in lithium fluoride by recoiling fission fragments and that we are dealing with linear regions of lattice damage, although in potassium bromide there is some evidence for the production of dislocations by this means.

A further development of interest is noted after prolonged soaking without agitation of the bombarded crystals in the etch solution. Fig. 4 is an optical micrograph (× 1,260) of etch pits developed in the unstirred reagent in 42 min. at 12° C. It will be seen that although some of the pits are regular square pyramids, others have developed a small number of pronounced steps. Similar pits have been observed by Whapham for etch pits originating on dislocations, and in explanation he has suggested that a dislocation inadvertently introduced during rough handling may become trapped at the centre of a flat pit formed at an earlier stage. This mechanism appears realistic in the case of flat-bottomed etch pits originating at dislocations which have afterwards moved on along a slip line, but can scarcely apply to pits originating at recoil tracks.

Noting that small, rapidly formed etch pits show a regular terraced structure, we propose that these terraces are probably composed of {100} planes parallel to the crystal surface and {110} planes normal to the crystal surface. On prolonged soaking the relative areas of these planes become redistributed in favour of decreasing {110} area even in the absence of overall dissolution. According to the estimates of van Zeggeren and Benson[4], the surface energies, not allowing for surface polarization, are 832 and 169 ergs cm.$^{-2}$ for the {110} and {100} faces, respectively. This is quite consistent with the view that a regular square pyramidal pit in contact with mother liquor is inherently unstable and will eventually break down into a large flat-bottomed pit containing a small pit at the centre.

I am indebted to Dr. W. M. Lomer and to Dr. A. D. Whapham for useful discussions. Mr. J. A. Coiley took the electron micrographs.

EFFECT OF HYALURONIDASE ON CAPILLARY PERMEABILITY, LYMPH FLOW AND PASSAGE OF DYE-LABELLED PROTEIN FROM PLASMA TO LYMPH

By Dr. G. SZABÓ
First Department of Medicine, University Medical School, Budapest

AND

S. MAGYAR
Department of Pathophysiology, Institute for Experimental Medicine, Hungarian Academy of Sciences, Budapest

According to previous reports[1–3] hyaluronidase seems to exert a distinct effect on the capillaries, increasing their permeability. This assumption, however, is not definitely proved. Hæmoconcentration, increased loss of fluid and of injected dyestuff from the circulation produced by hyaluronidase can equally well be accounted for by intravascular pooling of blood plasma[4,5].

Proteins leaving the circulation appear in the extravascular fluid. Tissue fluid, which forms the greater part of the extravascular fluid, can, under normal conditions, scarcely if ever be collected in sufficient amounts for analysis. Colloidal molecules entering the extracellular fluid also appear almost instantaneously in the lymph. We hoped, therefore, to obtain further information on the effect of hyaluronidase by investigating the composition and flow of lymph.

All investigations were carried out on dogs under hexobarbital anæsthesia (0·1 gm./kgm.). In the first series we tapped the thoracic duct in the neck and also the cervical lymph trunks on both sides with plastic tubes. In the second series of investigations lymph was collected from the lymphatics of the liver and the small intestine. The dogs received 1,000 V.R.U. of bacterial hyaluronidase (Hyason Organon) intravenously, followed immediately by 0·1 ml./kgm. of a 0·1 per cent solution of Evans blue, also intravenously. Lymph was collected for three periods of 15 min. each before the administration of hyaluronid-

ase and afterwards for four further periods ; the first two of 15 min., the others of 30 min. Lymph flow, the concentration of Evans blue in lymph and plasma, arterial blood hæmatocrit, and the concentration of total protein in plasma and lymph were determined before and after administration of hyaluronidase.

Hyaluronidase produced a small but significant rise of the arterial blood hæmatocrit in all experiments, but there was no significant change in total protein concentration of the plasma (Table 1).

Lymph flow increased in all vessels investigated. The most marked increase of flow-rate was recorded in the thoracic duct ; there was also an increase of lymph flow from the liver and the intestines (Table 2). An analysis of the results showed that the increase of lymph flow was statistically significant if expressed as percentage of that before administration of hyaluronidase.

The disappearance of Evans blue from the circulation and the appearance of the dye in the lymph was enhanced by hyaluronidase. It has been shown that this dye is quite firmly bound to protein *in vitro*[6,7] and *in vivo*[8,9]. Therefore, we believe that the passage of dye from plasma to lymph marks that of the protein it labels. To confirm this assumption we investigated simultaneously the disappearance from the plasma and the equilibrium between plasma and lymph of Evans blue and dextran (mean molecular weight, 60,000) and also of human serum albumin labelled with iodine-131[4,5,10], and found a good agreement between the different substances. The disappearance of the labelled protein was estimated by the following equation[11] :

$$k = \frac{\ln (V_1C_1) - \ln (V_2C_2)}{T_2 - T_1}$$

where k is the fraction of dye (labelled protein) disappearing from plasma per min. ; V_1 is the plasma volume before administration of hyaluronidase, V_2 the plasma volume 90 min. after administration of hyaluronidase, C_1 and C_2 the concentrations of dye in plasma and T_1 and T_2 the times of drawing the respective specimens of plasma. Hyaluronidase produced a definite increase in the amount of dye disappearing from plasma. In eighteen normal controls this was 0·00225 (standard deviation 0·000827) ; after hyaluronidase administration (in

thirteen dogs) this rose to be 0·00333 (standard deviation 0·000655). The difference is highly significant ($P < 0·001$).

We also investigated the equilibrium of labelled protein between blood and lymph. As a convenient way of expressing the passage of labelled protein, the concentration of dye in the lymph was calculated as a percentage of the mean plasma concentration. Table 3 shows a significant increase of relative concentration in the lymph of all the vessels investigated. We were, however, unable to collect sufficient amounts of lymph for estimation of dye concentration in the cervical duct, but we gained the impression that cervical lymph also contains more dye after injection of hyaluronidase.

Finally, there was a small non-significant increase in the total protein concentration in the lymph (Table 4).

This evidence, in agreement with the findings of other workers, leaves no doubt that the permeability of the capillaries is increased by hyaluronidase. There is not only an increased leakage of dye, but after administration of hyaluronidase the transfer of labelled protein between plasma and lymph is also enhanced. Furthermore, there is a definite increase in lymph flow. All these findings point to an increased protein and fluid transfer from the capillaries to the extracellular fluid. The increase of capillary permeability is quite general and could be detected in all the areas studied. The effect of hyaluronidase is of short duration only.

It is interesting that there were no significant changes in the total protein content of the lymph. The maximum concentration of Evans blue in the lymph was identical in the dogs receiving hyaluronidase and in the untreated controls. Although, in the short experimental period, equilibrium between plasma and lymph was not attained, towards the end of this period there was no significant difference of relative dye concentrations between the controls and the treated animals. These results point to the further possibility that a moderate increase of capillary permeability—in spite of a marked protein leakage—does not necessarily increase the protein content of lymph, nor perhaps that of the tissue fluid. The protein leaving the capillaries, if it does not exceed a certain amount, can be cleared from the extracellular compartment by the increase of the lymph flow alone, without increasing the protein concentration in the lymph.

GRAVIMORPHISM IN TREES

Effects of Gravity on Growth, Apical Dominance and Flowering in Fruit Trees

IT has long been claimed by horticulturalists that downward training of the branches of fruit trees reduces vegetative growth and promotes flowering[1–4]. These reports suggest that the position of the shoot in relation to the gravitational field may affect growth and flowering, but there appear to have been very few rigorous investigations of these effects in trees. A detailed investigation of the effects of gravity on growth, apical dominance and flowering in fruit trees was accordingly commenced in 1956.

The effect of the orientation of the shoot on its growth was investigated in apples, cherries, plums and blackcurrants, using 'maiden' trees planted in pots and restricted to a single shoot in the second year. The growth of trees maintained horizontally throughout the growing season was compared with that of the vertical controls for each species. The horizontal position was obtained by placing the whole plants and their pots horizontally. One group of horizontal plants was maintained with the same side of the plant uppermost throughout the period of treatment, while the plants of a second group were rotated through 180° twice each day. The treatments were commenced shortly before bud expansion in the spring. For watering, the horizontal plants were placed erect for 1–2 minutes, as required; to eliminate possible differential effects due to rain, the soil surface of the pots of the vertical series was covered with polyethylene sheeting. In order to maintain the experimental material as uniform as possible, all lateral shoots were removed as they emerged. In blackcurrant, there was a marked tendency for the outgrowth of laterals from the upper side of the stem, as has also been reported for citrus[5]. The extension growth was measured weekly throughout the growing season and the mean total extension-growth for the various experimental groups is given in Table 1.

In all species, the total growth of the horizontal trees was markedly less than that of the vertical controls, and the effect of the horizontal position was accentuated when the plants were rotated. In the cherries and plums the reduced total growth was due both to a smaller number of internodes and to reduced internode length, in the horizontal trees. In the apples and blackcurrants the difference in extension-growth was mainly due to differences in internode-length. Reduced hypocotyl extension in inverted seedlings of various species was reported by Hering[6].

Table 1. EFFECT OF SHOOT POSITION ON EXTENSION GROWTH

Species and treatment	No. of plants	Mean extension growth (cm.)	Mean inter-length (cm.)	Mean No. of inter-nodes
Cherry, Mazzard *F*12/1				
Horizontal, rotated	16	15·4 ± 1·4*	1·3	12
Horizontal, non-rotated	16	21·4 ± 1·7	1·5	14
Vertical	16	51·8 ± 2·1	2·5	21
Apple rootstock, No. 3436				
Horizontal, rotated	19	46·9 ± 1·5	1·4	32
Horizontal, non-rotated	19	52·9 ± 2·1	1·7	31
Vertical	19	69·3 ± 2·1	2·1	33

* Standard error.

A number of experiments has been conducted to investigate the interaction between apical dominance and the effects of gravity, and the results of two such experiments are given in Table 2. In these experiments, one-year stool-bed layers of apple rootstock *MM* 111 were pruned back to a height of 24 inches, and the subsequent growth was restricted to the laterals from the uppermost three buds. The resulting lateral shoots were trained as indicated.

From the results it is apparent that the growth of all shoots is less when they are in a horizontal position as compared with the vertical, but the uppermost shoots show a greater percentage reduction when trained horizontally than do the lower shoots (Experiment 1). As a result, there is relatively little difference in growth of the three shoots when they are all trained horizontally, so that only slight apical dominance is manifested. On the other hand, when all the shoots are trained vertically, the greater growth of the uppermost shoots results in well-marked apical dominance. Thus, it appears that the apical dominance exhibited by the uppermost shoot is only manifested when it occupies a vertical position. Since the lateral shoots usually grow out at an angle removed from the vertical, this will tend to reduce their growth further and to accentuate the apical dominance of the vertical leader.

The orientation of the shoot also has a marked effect on flower-initiation in apple rootstock No. 3436. None of the one-year maiden apple layers used in the experiment on extension-growth, described above, initiated flowers in 1956. The treatments were continued with the second year, however, and marked differences in flower-initiation were then observed. The 2-year-old layers grown in the normal vertical position initiated relatively few flowers, but the layers grown horizontally, both 'rotated' and 'non-rotated', showed heavy flowering on both 'spurs' of the 2-year shoots and also on the 1-year shoots (Table 3). The vertical trees, instead of forming spur-shoots on the 2-year shoots, formed short lateral vegetative shoots. Thus, the orientation of the shoot in relation to gravity has a marked effect on flower-initiation in apple. Similar effects were observed also in cherries, although the number of flowering buds was much smaller than in apples (Table 3). Effects of gravity on flower-initiation have also been reported for pineapple[7] and soybeans[8].

Table 2. EFFECT OF GRAVITY ON APICAL DOMINANCE

	Lateral No.	Shoot position*	No. of plants	Mean extension growth (cm.)
Exp. 1	1st	*V*	12	66·2 ± 2·6
	2nd	*V*		58·4 ± 3·4
	3rd	*V*		50·2 ± 3·1
	1st	*H*	12	42·4 ± 2·0
	2nd	*H*		40·6 ± 1·6
	3rd	*H*		39·6 ± 2·3
Exp. 2	1st	*V*	10	44·0 ± 2·0
	2nd	*V*		33·4 ± 3·4
	3rd	*V*		30·7 ± 1·5
	1st	*V*	8	49·2 ± 7·2
	2nd	*H*		26·8 ± 2·3
	3rd	*H*		27·3 ± 2·9

* *V*, vertical; *H*, horizontal.

Table 3. EFFECT OF GRAVITY ON FLOWERING

Species and treatment	No. of plants	No. of flowering buds	
		2-yr. shoots	1-yr. shoots
Apple rootstock No. 3436			
Horizontal, rotated	19	40	76
Horizontal, non-rotated	19	63	98
Vertical	19	1	4
Cherry, Mazzard *F*12/1			
Horizontal, rotated	16	1	0
Horizontal, non-rotated	16	19	0
Vertical	16	0	0

These effects of gravity on growth and flowering are clearly related to geotropism. Since, however, the latter term is used to describe a growth curvature, it is not strictly appropriate for the phenomena reported here, for which it is proposed to introduce the term 'gravimorphism'.

The plant material for these investigations was supplied by East Malling Research Station, the assistance of which in this respect is gratefully acknowledged.

Effect of Gravity on Flowering and Shoot Growth in Japanese Larch (*Larix leptolepis*, Murray)

PARALLEL with the investigation into the effects of gravity on growth and flowering of fruit trees[1], a series of experiments is also being carried out with forest trees. Species of *Pinus*, *Larix*, *Fagus* and *Betula* are being studied, but the present report deals chiefly with Japanese larch (*Larix leptolepis*, Murray).

While for fruit trees there is a certain amount of evidence from the experience of horticulturalists that gravitational effects may be of importance, there is little suggestion in the literature that this applies also to forest trees. However, Matthews and Mitchell[2], working on methods of training forest trees for heavy seed production, record that "nine-year-old Japanese and hybrid larch treated to form espaliers produced a great density of male and female flowers".

In order to investigate rigorously whether the actual position of the shoot relative to gravity influences the flowering of Japanese larch, an experiment was carried out in which branches were trained into horizontal and into downwardly directed positions, an equivalent branch in the same 'whorl' being left in its natural upwardly curving ('upswept') position as a control. In some cases a further branch was fixed in its existing position to prevent any tendency to sag during the course of the experiment. The treatments were applied between the end of March and the end of April 1957 to 2–5-year-old branches on trees 10–12 years old which had not up to that time borne an appreciable number of flowers.

By autumn 1957 the flower buds for 1958 were clearly visible, and it was found that out of 12 treated trees 10 showed more flowering in horizontal and particularly in downwardly directed treatments than in the controls, the difference being very marked in 8 trees. As many as 200 flowers, mainly male but including some female, had been induced on some branches, compared with three or four flowers on the untreated branch. The remaining two trees did not flower at all, possibly because they were smaller than average. They are excluded from Table 1, as is one other tree which started flowering heavily in 1958 in any event.

Table 1. EFFECT OF GRAVITY ON FLOWERING IN JAPANESE LARCH

	Branch fixed in existing position	Control branch (unfixed)	Branch fixed in horizontal position	Branch fixed in downwardly directed position
Total number of flower buds	21	90	647	1,079
No. of branches involved	11	16	13	12
Average number of flower buds per branch	2	5·5	50	90

The flowering of young Japanese larch is thus markedly influenced by the position of the branches in relation to the gravitational field, the greater the branch angle (measured from vertically upwards) the heavier the flowering. In addition, the trees have been brought into heavy flowering at an age when they would normally bear few or no flowers.

It seems probable that this 'gravimorphic' effect is important also in the normal reproductive development of larch. It is well known that in trees of many species the vigorously growing young branches are upwardly directed, generally growing out at an angle which is characteristic of both the species and the individual tree. With increasing age, the branch angle usually becomes greater so that the branch often comes to assume a horizontal or even downswept position, no doubt partly or wholly due to its increasing weight. From the results of the foregoing experiment it seems clear that this natural change in branch angle will tend to favour the onset of the flowering phase in young trees. Further evidence in support of this view is seen in the fact that the unfixed control branches generally had appreciably more flowers than those branches which were fixed in their existing position at the beginning of the season. It was also noted that in trees with a naturally flatter type of branching, the unfixed controls generally bore more flowers than in trees where the branches were very upswept.

In addition to inducing flowering, the horizontal and downwardly directed training in the foregoing experiment markedly reduced extension growth during 1957. Table 2 gives the measurements for the leading shoots of the branches.

Similar marked reduction in extension growth was produced in birch (*Betula verrucosa*, Ehrh.) by pulling down individual branches.

Table 2. EFFECT OF GRAVITY ON EXTENSION GROWTH IN JAPANESE LARCH
(Means of 11 branches)

	Control branch (unfixed)	Branch fixed in horizontal position	Branch fixed in downwardly directed position
Mean extension growth of main branch axis (cm.)	29·5 ± 2·3*	17·5 ± 1·5	14·0 ± 1·6
As a per cent of control branch	100	59·5	47·5

* Standard error of mean.

Gravity appears also to affect the distribution of flower buds on the individual larch twig. They may be seen to occur mainly on the lower sides of horizontally inclined twigs, and on all sides of the trailing twigs which are frequently found in this species. Now since the buds point forwards on the twigs at an angle of approximately 60–70° it would be expected that the flower buds on these horizontal and trailing twigs would point either downwards or horizontally, but not upwards. Quantitative verification of the observed distribution of flower buds can therefore be obtained by measuring the direction in which a large number of flower buds point in relation to gravity. Table 3 gives the results for two 5-year-old branches taken from trees which had recently commenced flowering.

Table 3. DISTRIBUTION OF MALE FLOWER BUDS IN RELATION TO GRAVITY

Direction in which buds point	Angle (measured from vertically upwards)	Branch 1		Branch 2	
		No. of flower buds	Per cent	No. of flower buds	Per cent
Upwards	0° –22½°	—	—	—	—
½ up	22½°–67½°	2	1	5	3
Horizontally	67½°–112½°	48	30	49	31
½ down	112½°–157½°	77	47	82	52
Downwards	157½°–180°	36	22	23	14
		163	100	159	100

It is seen that an average of 98 per cent of the flower buds point either downwards or horizontally. Although this confirms the observation that there is a clear-cut zoning of the flower buds to loci in which they will point downwards or horizontally, it is not yet clear whether the response of the bud is directly determined by its own orientation in relation to gravity, or whether it is determined by the position of the twig or branch system on which it occurs.

In view of the generally accepted evidence that geotropic effects result from the differential distribution of growth-hormone in response to gravitational stimuli, a similar mechanism for these 'gravimorphic' effects may be expected. This problem is being investigated.[1]

This work was carried out with the aid of a grant from H.M. Forestry Commission, which also kindly supplied the trees for the experiments. Acknowledgments are especially due to Mr. J. D. Matthews of the Forest Genetics Section, who has been closely associated with this project.

Polar Wandering, a Random Walk Problem

It has often been supposed that due to redistributions of mass the body of the Earth as a whole has shifted relative to its rotational axis, which has remained fixed relative to the Sun. It is convenient to think of this as movement of the pole over the surface of a fixed Earth. Since the Proterozoic the pole appears to have been displaced by as much as 90° of arc to its present position. Orogenic or epeirogenic movements and ice-cap melting or formation with the attendant fluctuations in sea-level are usually cited as possible causes of polar wandering. Darwin[1] and Kelvin[2] first discussed the dynamic stability of the Earth. Gold[3] and Munk[4] have recently re-examined the problem and have concluded that such large displacements of the pole could be a consequence of such geological activities.

The position of the pole may be obtained from the average direction of remanent magnetization of rock formations when the hypothesis[5] is made that the Earth's magnetic field, when averaged over a few thousand years, has approximated to a geocentric axial dipole. It has been customary to connect these pole positions[6] by curves passing from the Pacific Ocean along the east coast of Asia to the position of the present pole. But since the geological events which may have been responsible for polar wandering have been irregular, both in their type and in their distribution and timing, they are likely to have produced random polar movements. In this communication an attempt is made to fit the palæomagnetic data to a random walk of the pole over the Earth's surface.

If the sampling area has undergone continental drift, the polar wandering rate would have the drift velocity superimposed upon it, and both would be present in the palæomagnetic data. In this work the pole paths relative to Europe and North America have been used because their similarity in shape and direction suggests that neither continent has been displaced in latitude relative to the other to any great extent, but it has to be borne in mind that errors may arise from this source. The simplest case of a random walk is that on a plane, and provided the individual displacements are small and the total displacement does not greatly exceed 90° of arc it is not essentially different from a random walk on a sphere.

The probability density $w(\psi)$ that the pole will have an angular displacement ψ from the present pole at a time t is given by:

$$w(\psi) = \frac{2\psi}{C^2kt} \exp\left(-\frac{\psi^2}{C^2kt}\right) \qquad (1)$$

where C^2 is the mean square of the individual steps in the walk and k is the number of steps per unit time. The mean value of the angular displacement at time t is given by:

$$\int_0^\infty \psi\, w(\psi)\, d\psi \qquad (2)$$

$$= \int_0^\infty \frac{2\psi^2}{C^2kt} \exp\left(-\frac{\psi^2}{C^2kt}\right) d\psi \qquad (3)$$

$$= \tfrac{1}{2}\, \pi^{1/2}\, C(kt)^{1/2} \qquad (4)$$

and the mean value of the square of the displacement is C^2kt. Thus ψ is expected to vary linearly with $(kt)^{1\cdot 2}$ and points, the co-ordinates of which are $(\psi, t^{1/2})$, will be scattered along the line $\psi = C(kt)^{1/2}$. The limits for ψ at a probability of 0·95 are:

$$\psi_u = \varepsilon_u C(kt)^{1/2} \qquad (5a)$$

$$\psi_e = \varepsilon_e C(kt)^{1/2} \qquad (5b)$$

where the factors ε_u and ε_e are given by:

$$0{\cdot}025 = \exp(-\varepsilon_u^2)$$

and

$$0{\cdot}975 = \exp(-\varepsilon_e^2)$$

respectively. Thus ψ lies between the limits 1·92 $C(kt)^{1/2}$ and 0·16 $C(kt)^{1/2}$ at $P = 0{\cdot}95$.

In Fig. 1 the displacements are plotted against the square root of time, the results from Western Europe and North America being indicated by full and open circles, respectively. The straight line through the origin which best fits these data by least squares is given by

$$\psi = 3{\cdot}0\, t^{1/2} \qquad (6)$$

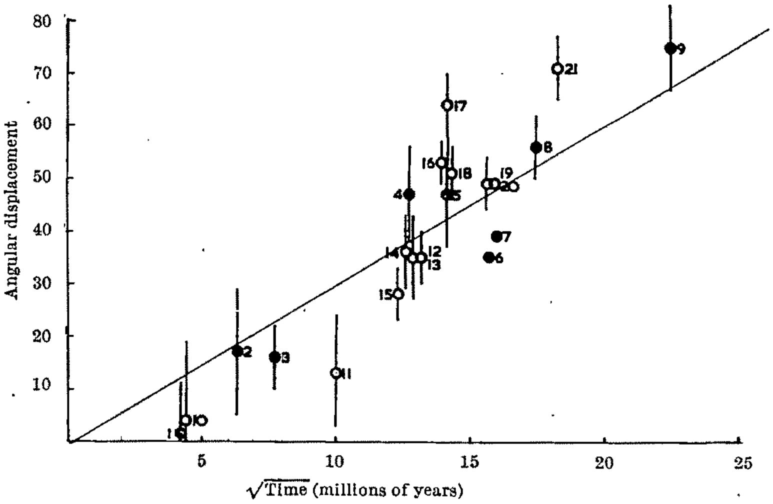

Fig. 1. The angular displacement of the pole from its present-day position is plotted against the square root of time in millions of years. The pole positions used are numbered as follows: 1, Miocene lava, France; 2, Oligocene intrusives, France; 3, Eocene lavas, Northern Ireland; 4, Triassic marls, England; 5, Permian traps, Exeter; 6, Carboniferous millstones, Derbyshire; 7, Carboniferous toadstones, Derbyshire; 8, Devonian sandstones, Wales; 9, Cambrian sandstones, Wales; 10, Upper Tertiary lavas, Washington; 11, Cretaceous sandstones, Colorado plateau; 12, Triassic sandstones, Springdale; 13, Triassic lavas, Holyoke; 14, Triassic lavas, sediments, Connecticut; 15, Triassic sequence, New Jersey; 16–18, Permian Supai beds, Arizona; 19, Carboniferous sandstones, Arizona; 20, Carboniferous concretion, Texas; 21, Silurian sediments, Maryland. The vertical lines through the pole positions represent the error (at $P = 0{\cdot}05$) in determining the latitude. The European and North American results are indicated by full and open circles respectively

where ψ is in degrees of arc and t is in millions of years. The expected value of 3° of arc for the magnitude of the displacement of the pole in one million years is a useful quantitative value for other workers interested in the mechanism of polar wander.

It is emphasized that since the movement of the pole may be considered to be a random walk, there will be, on one hand, periods during which there is effectively very little displacement of the pole (for example, the Quaternary) and, on the other hand, periods during which rapid displacement of the pole is in evidence (for example, Carboniferous[7]).

This work was carried out while I was a research student in the Department of Geophysics of the Australian National University at Canberra, A.C.T. I wish to thank my supervisors, Prof. J. C. Jaeger and Mr. E. Irving, for their criticism and helpful discussion.

Secular Variation in the Direction of Geomagnetism as the Standard Scale for Geomagnetochronology in Japan

It is well known that igneous rocks and ceramic objects are permanently magnetized in the direction of the Earth's magnetic field in which they were cooled from a high temperature. I have already pointed out that the baked earth in the hearths of prehistoric dwelling pits would be magnetized similarly, and that this could be applied to developing chronology for anthropology and archæology[1]. The term 'geomagnetochronology' may be defined as chronology from palæomagnetism.

In Japan three kinds of sources—hearths, furnaces and kilns—offer baked earth of various ages. A hearth is a simple fireplace made directly on the floor of a prehistoric dwelling pit, a furnace is a structure built up with sandy clay against the wall of a dwelling pit of the protohistoric and the historic ages, while a kiln is an ascending tunnel-like structure built with clay on the slope of a hill, in which ceramic wares were baked in historic times.

Samples of small blocks of baked earth, generally about ten in number, were collected from each fireplace and the remanent magnetism was measured with an astatic magnetometer. The mean direction of the remanent magnetism of each set was calculated by Fisher's method[2], and for comparison the data from samples from sites far from Tokyo were reduced to Tokyo by Nagata's procedure[3].

The samples can then be dated by comparing the direction of the remanent magnetism with a standard scale of the secular variation in the direction of geomagnetism in the past; thus it is essential to establish such a standard scale. This standard scale has been set up for the past 1,700 years and it is shown in Fig. 1. Encircled points indicate the geomagnetic inclination and the geomagnetic declination at known dates, most of which were reported or cited by Nagata and Kato[4]. Old records of geomagnetic observations gave the points 1613, 1694, 1802, 1827, 1854, 1860, 1887, and the curves from 1887 to the present, while measurements of the remanent magnetism of lava-flows dated by the descriptions of volcanic eruptions of 864, 1471, 1749, 1778 and 1779 in old documents gave the other encircled points. Besides these, points 1 and 2 represent the direction measured by me for samples of baked earth from two kilns, the dates of which are almost certainly known from the type of pottery as about 1300. These gave the curve of inclination for the period from 864 to the present shown in Fig. 1; the curve was then extrapolated for the time before 864 on the assumption that the inclination underwent a secular variation similar to that estimated for the period after 864. On this curve were plotted the inclinations obtained from sixty-five sets of samples of baked earth from hearths, furnaces and kilns of various ages; eighteen of these are shown as points 3–20. The declinations associated with these inclinations were then plotted, and the secular variation curve of declination shown in Fig. 1 was drawn so as to fit as many as possible of the points. The vertical lines at each point indicate the magnitude of the Fisher radius of the circle of confidence at the 5 per cent level.

Three sets of samples which yielded points well off the curves have been ignored for the present. The two curves thus obtained seem to be reasonably accurate, since almost all the points are in general

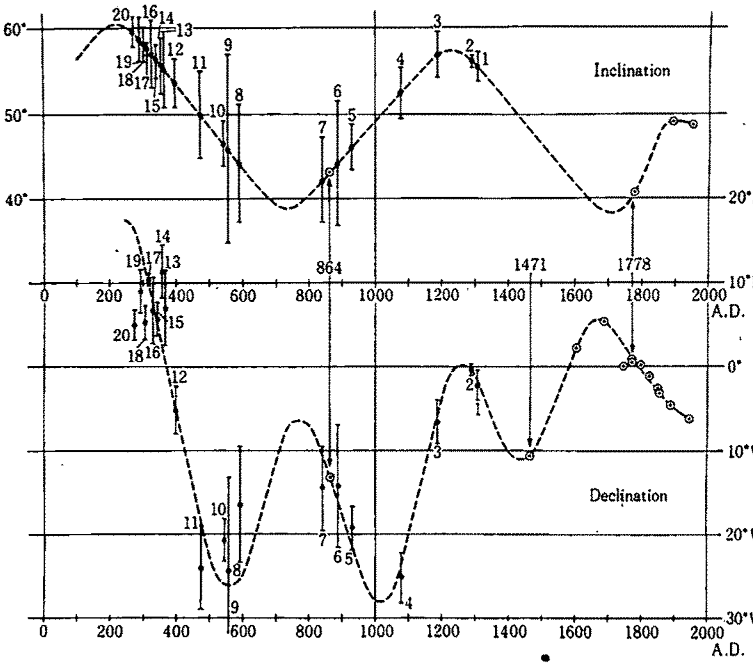

Fig. 1

Table 1

No. of samples	Declination D	Inclination I	Fisher's θ for $P = 0{\cdot}05$	Radiocarbon date
12	5·1° E.	49·2°	3·3°	4,546±220 B.P.
14	3·7° E.	50·6°	1·2°	5,100±400 B.P.
15	5·6° W.	48·2°	2·9°	
20	6·1° W.	48·9°	3·2°	

chronologically consistent with archæological evidence.

Although we have no specimens from before 864 which can be dated from records, radiocarbon assay can be used instead. At present two such assays are available for prehistoric Japan. One is that made by Libby, of the University of Chicago, on charcoal found on the floor of a dwelling pit at the shell-mound of Ubayama in the Chiba Prefecture[5]. I collected samples of baked earth from the floor of this dwelling pit and measured their remanent magnetism. The other radiocarbon date was obtained by Crane, of the University of Michigan, from a canoe excavated from a peat formation at Kamo in the Chiba Prefecture[6]. In this case there was no baked earth at the site, but I used samples from hearths of three dwelling pits which contained the same type of pottery as that associated with the canoe. These were at the shell-mound of Minamihori in the Kanagawa Prefecture. The results are presented in Table 1.

In 114 sets of samples of various ages during the past 6,000 years or so, the direction of remanent magnetism generally fell within the range 40–60° for the inclination, and 20° E.–30° W. for the declination. This suggests that the secular variation in the direction of geomagnetism for the past 6,000 years is similar to that estimated for the past 1,700 years. Assuming this, the most probable secular variation curves of the direction of geomagnetism for a time range covering 4,546 and 5,100 years before the present were tentatively drawn as in Fig. 2. On these curves the results of twenty-four measurements on baked earth from hearths fell in positions consistent with the chronological order known from the types of pottery associated with them. One result, however, was well off the curve.

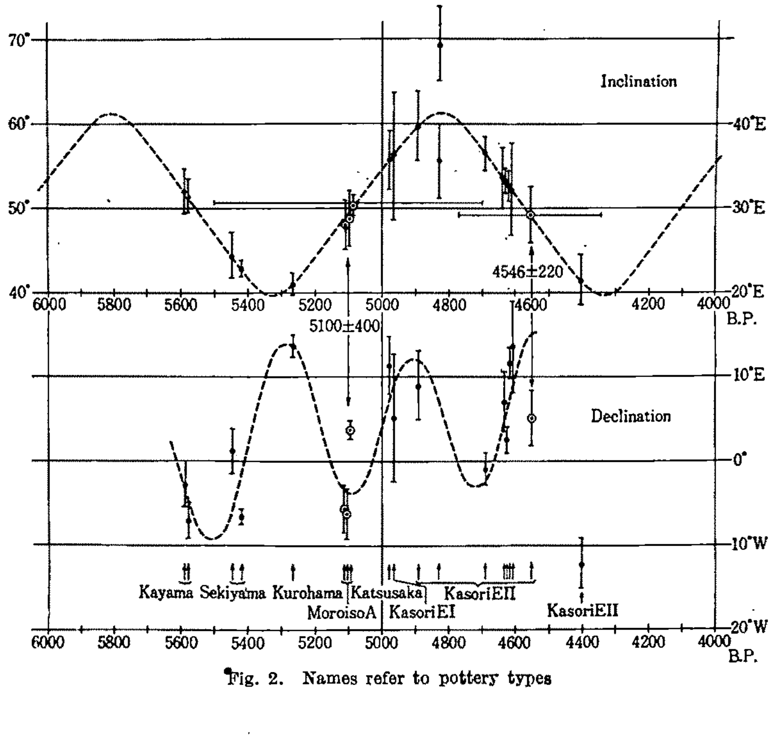

Fig. 2. Names refer to pottery types

Measurement of the Thickness of the Earth's Crust in the Albertan Plains of Western Canada

As a contribution to the International Geophysical Year, a group composed of Canadian, American and British oil interests and independent geophysical contractors has recently carried out a large-scale seismic refraction experiment in order to measure the thickness of the Earth's crust, or depth to the Mohorovičić discontinuity, in the Albertan Plains of western Canada.

Fifteen seismic parties using refraction equipment were spaced at roughly uniform intervals over a distance of 130 km. and two-way observations were made from 900-lb. buried charges of dynamite located at the extremities of this range. The line extended approximately parallel to the frontal thrust of the Rocky Mountains, between latitudes 50° 45′ N. and 51° 47′ N., and some 100 km. to the east of the thrust.

For the upper crustal material recorded as first events in both directions of shooting, the velocities were about 3·5 and 6·0 km./sec. The first represents Cretaceous shales and sands to a depth of 2·3 km. The second velocity represents the known Palæozoic limestones, and its event carried for the whole length of the line.

A later event with the characteristic time-distance relation of a reflexion shows a marked increase in energy content at a distance not less than about 100 km. where its velocity is about 8·2 km./sec. This event has been ascribed to reflexions from the Mohorovičić discontinuity amplified by refractions from beyond the critical angle, and the time distance variation of this event is almost identical in both directions of shooting, thus indicating an absence of dip.

Using the above velocities, the depth to the Mohorovičić discontinuity is computed to be about 36 km. However, the velocity of 6 km./sec. is not necessarily representative of the whole of the crustal material from the Palæozoic to the Mohorovičić discontinuity, and one would be justified in assigning a somewhat greater velocity than this in the depth calculation and thereby derive a greater depth. Taking a value of 6·3 km./sec. as an average of all published velocities for the crust under North America, the depth to the Mohorovičić discontinuity becomes about 40 km. Furthermore, other distinct events with a velocity of about 7·2 km./sec. have been recorded, and if these are associated with refractions from the lower part of the crust, the depth to the Mohorovičić discontinuity must be increased on this account. A re-computation, including the data from these events and adhering to the velocity of 6·0 km./sec. for the upper layer, yields a total depth to the Mohorovičić discontinuity of 47 km.

The range of depths thus indicated (40–47 km.), suggests that the crust in the western Albertan plains is thicker than the 30–35 km. that has been generally observed in plains areas elsewhere in the world[1]. It appears that crustal thickening that could be expected under the Rocky Mountains extends east of the mountain front at least by 100 km.

The 7·2 km./sec. layer which is inferred to lie at a depth of about 25 km. may be comparable with a 7·0 km./sec. zone observed at the same depth by Hodgson[2] in eastern Canada, and a 7·2–7·4 km./sec. layer noted at 20 km. in California and Nevada by Press[3]. The relatively weak waves refracted from this interface were observed as second events on our records. It is not likely that they could have been identified without multi-trace recording equipment of the type used in seismic prospecting which has been put to good account in the U.S.S.R.[4]. These observations and others recently reported from Europe tend to support the existence of the discontinuity first inferred by Conrad[5] and believed by some seismologists to represent an interface between 'granitic' and 'gabbro' layers within the crust.

It will be interesting to see how this result co-ordinates with the seismic measurements made at the time of the Ripple Rock explosion, since one of the observation stations recording this explosion coincided with one of the shot points in the refraction experiment.

A fuller account of this experiment will be published at a later date.

Influence of the Semi-Permanent Low-Level Ocean Duct on Centimetre Wave Scatter Propagation beyond the Horizon

Since 1949, the Admiralty Signal and Radar Establishment has conducted a number of short-term investigations on the propagation of centimetric radio waves over sea, at ranges well beyond the radio horizon. Some details of this work have been given recently by Joy[1,2]. It has been shown that, at frequencies of about 10,000 Mc./s., the extra-diffraction signal-levels relative to free space are invariably some 10–15 db. lower than the corresponding levels at 3,000 Mc./s. at all ranges beyond the radio horizon. However, the signal attenuation-rate with distance is very similar at these two frequencies. The observed difference in signal-level is apparently inconsistent with available theories[3,4] of radio wave scattering in the troposphere, and Starkey *et al.*[5] have suggested that it provides support for the alternative theory of layer reflexions from refractive index discontinuities in the lower atmosphere.

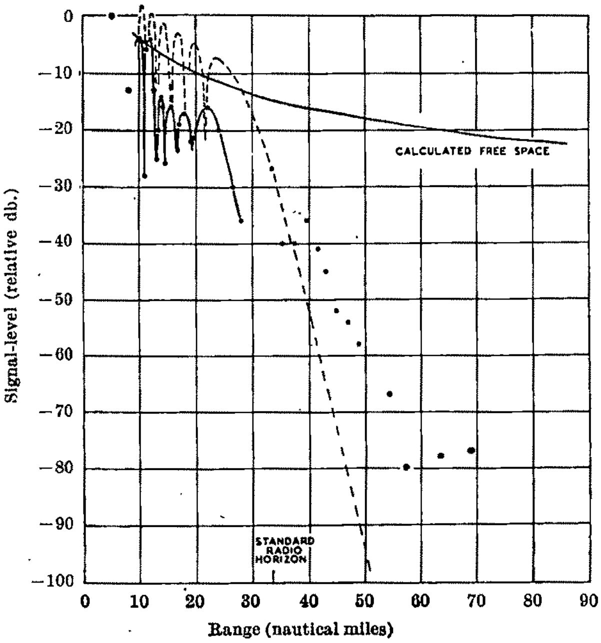

Fig. 1. – – – –, Theoretical interference and diffraction curve for standard atmosphere. Transmitter aerial height, 60 ft.; receiver aerial height, 400 ft.

A significant feature of this Establishment's measurements of signal strength as a function of range at 10,000 Mc./s. over sea paths is that there is a similar degradation in the overall level of the interference pattern relative to the free-space level at ranges approaching that of the radio horizon. Examples of measurements made in the North Sea during the spring of 1956 and in the English Channel in spring 1957 are given by Joy[2]. Examples of further measurements made in the English Channel in the winter of 1957 and spring of 1958 are shown in Figs. 1, 2 and 3.

Fig. 1 shows the interference pattern obtained with a shipborne transmitter aerial at 60 ft. and a land-based receiver aerial at 400 ft. above sea-level. The interference maxima which correspond to the lobes in the vertical coverage diagram at elevations greater than about 0·4° relative to the Earth tangent (ranges less than 12 nautical miles) attain the free-space level while the maxima corresponding to lobes at smaller elevations are depressed by about 12 db. below their theoretical levels.

Figs. 2 and 3 show measurements made using a land-based receiving equipment at 50 ft. and a 10,000 Mc./s. airborne transmitter at 100 ft. and 250 ft. above sea-level respectively. With the transmitter at 100 ft. the theoretical signal-level is approached at elevations exceeding about 1° (ranges less than 1 nautical mile) while for the 250 ft. run

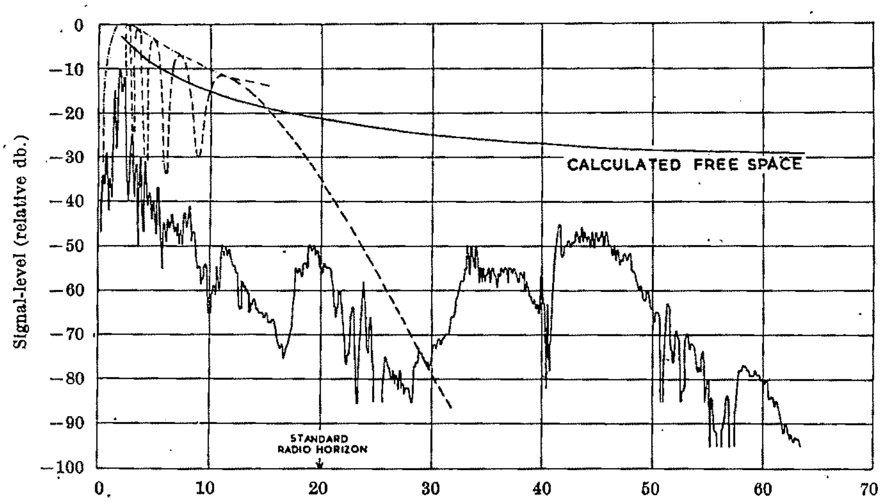

Fig. 2. — — —, Theoretical interference and diffraction curve; —·—·—, theoretical envelope of interference maxima taking account of aerial vertical polar diagrams (all for standard atmosphere). Transmitter aerial height, 100 ft.; receiver aerial height, 50 ft.

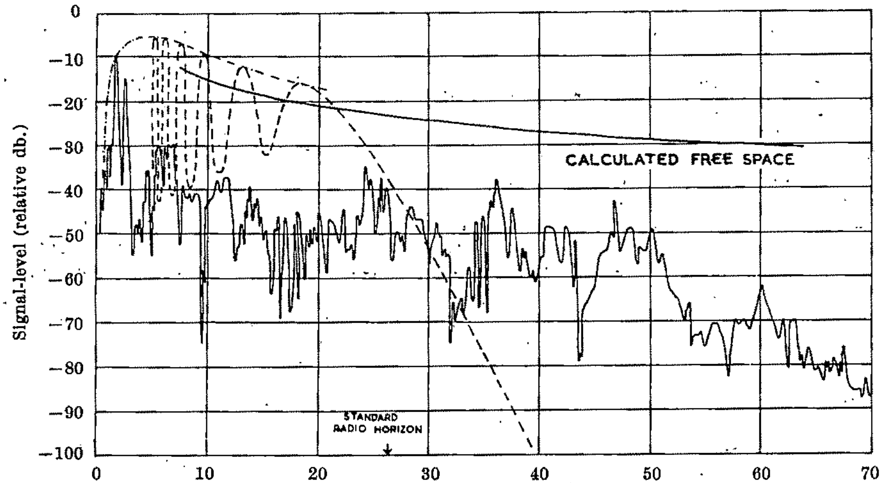

Fig. 3. — — —, Theoretical interference and diffraction curve; —·—·—, theoretical envelope of interference maxima taking account of aerial vertical polar diagrams (all for standard atmosphere). Transmitter aerial height, 250 ft.; receiver aerial height, 50 ft.

the elevation also exceeds about 1° (ranges less than 2 nautical miles).

The distortion of the vertical coverage diagram at low elevations results from the diversion of almost horizontally directed energy by the semi-permanent low-level ocean duct[6]. The energy diverted from the lowest lobes is guided near the surface of the sea well beyond the horizon. With receiving aerials sited relatively high, the surface-guided component of the signal beyond the horizon is not directly observable (Fig. 1). However, with relatively low receiving aerials, the surface-guided energy is clearly apparent (Figs. 2 and 3). Day-to-day variations in the observed signal are experienced as the magnitude and intensity of the duct change.

Since only the low-level lobes contribute to radio wave scattering in the lower troposphere, it follows that any diversion of energy from these lobes will result in correspondingly less power entering the volume common to the transmitter and receiver aerial beams and being scattered in the receiver direction. It follows, therefore, as suggested by Richards[7], that for purposes of applying a scattering theory to the extra-diffraction signal at 10,000 Mc./s. the measured free-space level of the contributing lobes should be used instead of the theoretical value. When this is done there is no longer any marked discrepancy in signal-level at long ranges between 3,000 and 10,000 Mc./s. observations. Since the energy diverted from the lowest lobes at 10,000 Mc./s. reappears as an enhanced surface-guided component it follows that, at ranges well beyond the radio horizon, a high-sited receiving aerial will detect only a degraded scatter signal component, while a low-sited receiving aerial may detect a composite signal consisting of the degraded scatter component plus the surface-guided component. The relative contributions of the incoherent and coherent components in the latter case will vary with short-term variations in the magnitude and intensity of the low-level duct, while the median level of the total signal remains substantially unchanged. Such behaviour has in fact been observed[2].

The normally experienced characteristics of the low-level duct do not permit regular support of a surface-guided component over sea at 3,000 Mc./s. In fact, the extra-diffraction signal fields observed over the sea are in good agreement with the theoretical predictions of scatter theory. The present work makes it clear that the scatter mechanism itself is equally effective at 10,000 Mc./s., but that additional factors are involved in propagation over the sea beyond the horizon which may limit its effective exploitation.

Determination of Traces of Oxygen in Sodium Metal by Infra-red Spectrophotometry

THE principal methods for the determination of traces of oxygen in sodium metal are based on the titration of sodium monoxide after the metal has been amalgamated and the oxide filtered off[1,2]; distilled in vacuum[3,4]; or allowed to react with an alkyl halide[5]. A 2 gm. sample of sodium metal containing 50 p.p.m. oxygen contains 1·25 × 10^{-5} equivalents of sodium monoxide. In the alkyl halide method, the presence of a 7 × 10^3 fold quantity of sodium bromide introduces difficulties in the determination of sodium monoxide by conventional volumetric methods. Elsewhere this difficulty has been discussed and a solution suggested[6]. The amalgam and distillation methods also suffer from some disadvantages associated with quantitative separation and subsequent estimation of the oxide.

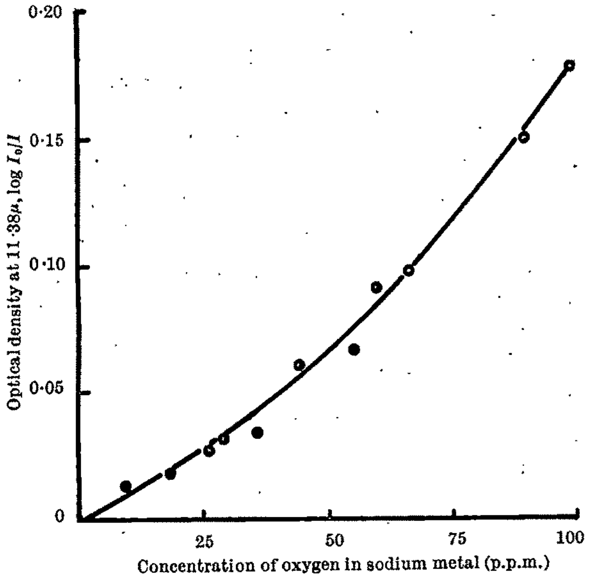

Fig. 1. Oxygen content of sodium metal by infra-red spectrophotometry

The use of an infra-red pressed-disk technique[7] with the alkyl halide method obviates difficulties associated with determinations of sodium monoxide in the range 5–100 p.p.m. in sodium metal. Following the reaction of the sodium metal with the alkyl bromide[5], the reaction mixture is dissolved in water and the unchanged oxide (now hydroxide) is converted into sodium bicarbonate by passing in excess carbon dioxide. The solution is then freeze-dried and the resultant powder heated at 400° C. for 2 hr. 1,500 mgm. of the sodium bromide–sodium carbonate mixture is then compressed to a clear disk by the usual technique[7]. Infra-red spectrophotometric analysis, using a Perkin Elmer model 21 infra-red spectrophotometer, shows absorption bands at 4·00, 6·93, 11·38 and 14·19μ. The absorbance at 11·38μ due to sodium carbonate is not subject to any interference, and although Lambert's law is not obeyed, from a standard curve (Fig. 1) the oxygen concentration in the original metal can be estimated with an accuracy of approximately 10 p.p.m. by weight.

The infra-red procedure also opens the way for the simultaneous determination of other impurities in sodium metal provided that they may be converted quantitatively to compounds with absorption bands in the infra-red region. Full details of the above method will be reported elsewhere.

A New Configuration of Deoxyribonucleic Acid

STRUCTURES for deoxyribonucleic acid in the *A* and *B* configurations have been described[1]. They are compatible with X-ray diffraction data and embody the base-pairing hypothesis suggested by Watson and Crick[2]. The results we describe here strengthen our belief that no alternative stereochemical hypotheses could be used to build models in agreement with the data.

We have observed a reversible transition between the *B* X-ray diffraction pattern of the lithium salt of deoxyribonucleic acid and a similar but distinct pattern we call *C* (Fig. 1). The transition from *B* to *C* is induced by lowering the relative humidity from 66 to 44 per cent. By slight alteration of the *B* model we have arrived at a model for *C* and accounted for the main differences between *B* and *C* diffraction patterns. The base pairs were moved by about 2 A. away from the helix axis, and tilted by about 5°; the pitch of the helix was altered so that there were 9·3 instead of 10 base pairs per turn.

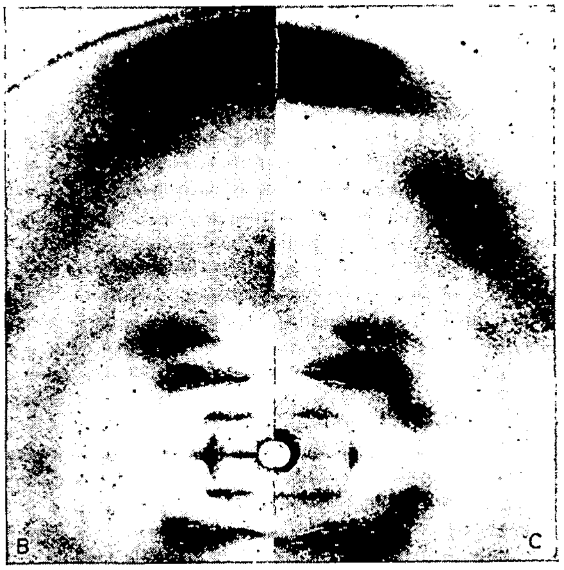

Fig. 1. Diffraction pattern of lithium salt of deoxyribonucleic acid in the *B* (left) and *C* (right) configuration

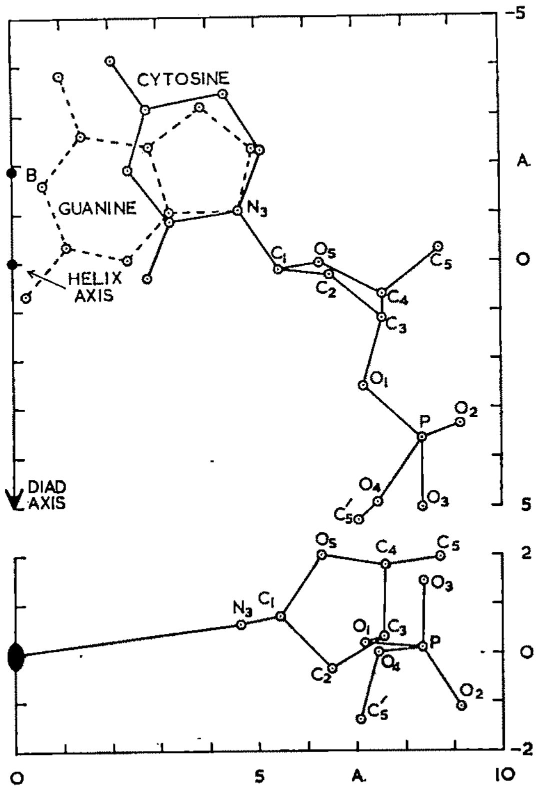

Fig. 2. A preliminary model of the *C* configuration of deoxyribonucleic acid showing approximate projection of a nucleotide on planes perpendicular to the helix and diad axes. *B* is the helix axis in the *B* configuration

In building a molecular model of deoxyribonucleic acid, there is considerable stereochemical freedom in arranging the components and there is, therefore, a small possibility that for any single configuration the agreement between observed and calculated diffraction might be fortuitous. This possibility now seems much smaller, because of our ability to follow the transition between two closely related configurations.

A full account of this work and that on the *B* configuration is being prepared. The work was greatly aided by computer time made available by I.B.M. United Kingdom, Ltd., and I.B.M. World Trade Corporation.

A Three-stranded Polyribonucleotide Structure

THE synthetic polymers, polyadenylic acid (*A*) and polyuridylic acid (*U*) interact strongly when mixed together in aqueous solution. Evidence for interaction on mixing comes from many observations, including increases in viscosity, sedimentation coefficient and molecular weight and decrease in ultra-violet absorption[1]. The last phenomenon, referred to as a hypochromic effect, is observed in the reverse fashion for deoxyribonucleic acid (P. Doty, private communication), that is, on thermal disruption of the double chain helical molecule in solution there is a substantial increase (about 30 per cent) in the optical density. This parallel behaviour of deoxyribonucleic acid and the chemically related synthetic complex suggests that their structures may be comparable. Added weight to this view is given by X-ray diffraction pictures[2] which show remarkable similarities between naturally occurring deoxyribonucleic acid and a synthetic fibre of polyadenylic acid/polyuridylic acid (*AU*) drawn from a solution containing equimolar portions of polyadenylic and polyuridylic acids. These facts have led Rich[3] to propose that the hydrogen bonding in the polyadenylic acid/polyuridylic acid complex is of the same type as that observed between adenine and thymine in deoxyribonucleic acid.

When the polyadenylic acid/polyuridylic acid complex is mixed in aqueous solution with varying proportions of polyuridylic acid, a maximum drop in the optical density is observed (under appropriate chemical conditions) when the two compounds are present in equimolar amounts[3]. Rich has suggested that this is due to the formation of a three-chain structure, containing one chain of polyadenylic acid and two of polyuridylic acid, and designated *AUU*. Furthermore it has been proposed that the original complex maintains its deoxyribonucleic acid-like structure and that the second chain of polyuridylic acid winds around the first two so as to form a triple helix. In such a structure the only way in which the second polyuridylic acid chain could form two strong hydrogen bonds with the complex is by hydrogen bonding from its O$_6$ and N$_1$ to the adenine N$_{10}$ and N$_1$ respectively. Disregarding the details of Rich's proposal for the moment, it is difficult to explain the spectrophotometric data other than by some sort of three-chain structure; confidence in this type of structure is increased by the observation[4] of a similar hypochromic phenomenon in a different system of polynucleotides containing a 1 : 2 mixture of polyadenylic and polyinosinic acids (*AII*). Unfortunately X-ray diffraction pictures of these three-stranded complexes are not available and, consequently, it is difficult to evaluate molecular models. Aside from purely stereochemical considerations, however, there is new chemical evidence that may be important in judging possible three-chain structures, and I wish to propose a new structure of *AUU* to which I have been led by chemistry rather than by X-ray diffraction.

The chemical evidence on which this new structure is based relates to Rich's observation[3] that the divalent cation, Mg^{++} or Mn^{++}, not only accelerates the reaction $AU + U \rightarrow AUU$ but that it also complexes to the extent of one or two ions per three nucleotides. The problem of binding to nucleic acid by magnesium ions has been studied and reported elsewhere[5,6], and the conclusion was reached that under appropriate conditions the ions[6] will react strongly with deoxyribonucleic acid at sites on the purines which contain configurations favourable for chelation. In particular, adenine in nucleic acid can chelate magnesium ions between the N$_7$ and N$_{10}$ positions of the purine, ring, but only when the plane containing the N$_{10}$ amino-group is turned out of the plane of the purine, because of the steric interference to chelation offered by the amino hydrogens. (It is possible that the amino hydrogens prefer to remain in the plane of the adenine because of the partial double bond character of the C_6—N_{10} bond. In adenine hydrochloride the C_6—N_{10} bond has a length[7] of 1·27 A., corresponding to more than 50 per cent double-bond character. Unfortunately, adenine is not directly comparable with its hydrochloride, since the formation of a resonant hybrid with a C_6—N_{10} double bond involves a separation of charge in the former. Thus one would expect the C_6—N_{10} to have more double-bond character in the hydrochloride. It seems clear that there will be some shortening of the C_6—N_{10} in adenine over the single bond-length, but in view of our ignorance as to its exact amount it is most difficult to say how much stabilization energy will result from this partial double-bond character.) Applying this information to the *AUU* system we see that here there is one purine per three nucleotides and therefore one site per three nucleotides for strongly binding the magnesium ion. The binding of magnesium ions by adenine in *AUU* necessitates the destruction of one of the original hydrogen bonds between the polyadenylic acid/polyuridylic acid double helix because of the required rotation of the N_{10} amino-group. Moreover, it will not be possible to make the hydrogen bonds between the second polyuridylic acid chain and the adenine suggested by Rich because the appropriate binding site on adenine is already occupied by the magnesium ion.

These considerations have led to the investigation of possible alternative structures for *AUU*, which have two strong hydrogen bonds per nucleotide and, furthermore, can accommodate the magnesium ion in the chelating position on adenine. In so doing it has been found that there is only one way of combining the three nucleotides which is sterically feasible. The scheme of hydrogen bonding involves a complicated system of tilts of the planes of the bases and is shown in projection in Fig. 1 for a nucleotide triplet. The hydrogen bond distances, N—H . . . *X*, are given in the figure and in all cases the deviation of N—H . . . *X* from linearity is less than 20°.

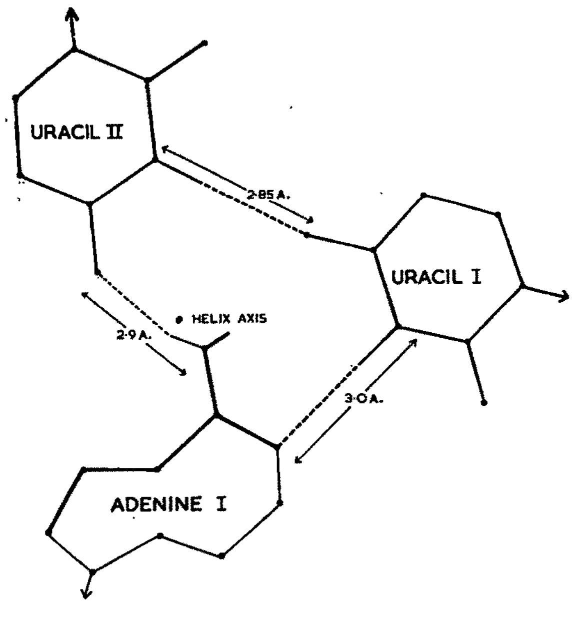

Fig. 1. Base pairing in three-stranded structure. The plane of adenine I is tilted about 44° relative to uracil I and about 37° relative to uracil II

Based on this system of nucleotide hydrogen bonding, a three-chain right-handed helical structure has been built. This model has a unit translation along the helical axis of 4·2 A. and a twist of 36° per triplet to give an exact repeat every thirty nucleotide residues or every ten residues along one chain. The sequence of atoms in the phosphate sugar backbone, which has an average diameter of 19 A., runs in the same direction in all three chains. Adenine I and uracil I (see Fig. 1) are related by a diad axis and as a result the backbone in the two polyuridylic acid chains runs in the same sense relative to the base groups as it does in deoxyribonucleic acid ; but the sense in the polyadenylic acid chain is opposite to that in deoxyribonucleic acid. The planes of the two uracil bases are tilted only a few degrees from the perpendicular to the helix axis, whereas the plane of the adenine is tilted about 40°. The bond distances have been determined to an accuracy of ± 0·15 A. and the bond angles are the same within ± 3° as those in the deoxyribonucleic acid *B* structure[8]. The OH on the C_2 of the ribose has no short contacts in this model except those inherent in the ribose ring. The shortest contact (2·9 A.) observed is that between the ring oxygen of the sugar and the C_4 position on the uracils. However, this could probably be increased by further adjustment. Since so few short van der Waals contacts exist it would appear that a structure of this type is possible ; but it should be emphasized that the dimensions of this model are arbitrary except for the specification of the hydrogen bonding between the nucleotides.

Although the *AII* polymer (mentioned earlier as showing the same hypochromic behaviour as *AUU*) has not been closely examined with models, the same type of hydrogen bonding appears to be possible.

It is interesting that the three-stranded structure for *AUU* proposed here involves molecular rearrangement in the original polyadenylic acid/polyuridylic acid complex prior to the attachment of a second chain of polyuridylic acid. The fact that the *AUU* complex does not form instantaneously in solution from a mixture of polyadenylic acid/polyuridylic acid +polyuridylic acid even under the most favourable conditions[3] must be due to the relatively high energy of the activated complex for its formation. The activated complex most likely involves a strained hydrogen bond between the adenine N_{10} and the uracil O_6 which is on the verge of breaking. It is easy to see that magnesium ions could lower the energy of the activated complex through the formation of a chelate with adenine. This lowering of the activation energy by magnesium ions would account for the fact that the *AUU* complex, although stable in media of high ionic strength lacking divalent cations, nevertheless forms much more rapidly in their presence.

The problem of deoxyribonucleic acid acting as a template for ribonucleic acid formation may be related to the structure of three-chain complexes of the type discussed here, and a specific coding mechanism, involving a three-chain complex as the template mechanism for making nucleic acids, has been proposed[9].

I would like to thank my colleagues at this laboratory for the use of molecular models and for advice and criticism, and also Prof. P. Doty for discussions on the solution chemistry of polynucleotides.

Note added in proof. X-ray pictures, on material containing a 1 : 2 molar ratio of polyadenylic and polyuridylic acids obtained in this laboratory on material given by R. F. Beers and R. F. Steiner, suggest modifications in the model described here. The X-ray pictures suggest that the unit translation along the helical axis be changed from 4·2 A. to 3·86 A. and the twist of 36° per triplet be changed to about 41°. In view of these results and the desirability of obtaining van der Waals contacts between the planes of the base groups, it now seems more reasonable to tilt both adenine I and uracil II about equal amounts (20°) and in the direction of the pitch of the helix. These preliminary results from X-ray diffraction necessitate more detailed consideration which will be presented elsewhere. However, it does not appear that there is any inconsistency with the chemical arguments presented here concerning the hydrogen bonding.

Vibrational Frequency associated with the Boron–Nitrogen Dative Bond in Amine Boranes

RESEARCH in the chemistry of boron has been extremely active in the past few years and its Lewis acid-base complexes have been of particular interest. Although the boron–nitrogen dative bond is one of the most stable of such bonds to boron and occurs in a number of important boron compounds, the vibrational stretching frequency of this bond in the rather few cases studied has been assigned an unexpectedly high value. For example, in complexes of boron trifluoride with ammonia[1] and nitrogen heterocycles[2], frequencies lying in the range between 980 cm.$^{-1}$ and 1,120 cm.$^{-1}$ have been assigned to this motion, in the complex of boron trimethyl with ammonia, a value of 1,105 cm.$^{-1}$ has been selected[3], and in the complex of borane (BH_3) with nitrogen trimethyl ($N(CH_3)_3$) a value of about 1,250 cm.$^{-1}$ has been given[4]. By way of comparison, frequencies assigned to the covalent carbon–carbon bond in halogenated ethane derivatives, where the masses involved are comparable, range from about 820 cm.$^{-1}$ to 1,075 cm.$^{-1}$. It is, of course, not always a proper comparison merely to look at the magnitude of frequencies in complete disregard of other factors. Nevertheless, chemical data in this case would seem to indicate a lower range for the stretching frequency of the boron–nitrogen dative bond.

We have just completed a Raman spectroscopic study of the 1 : 1 complexes of borane with ammonia and the three methyl amines, including several isotopic derivatives. The preparation of ammonia borane has been described recently[5] and the mono- and di-methylamine derivatives were prepared in similar fashion. The preparation of the trimethyl amine compound is well known. Spectra were obtained in solution in dimethyl ether or liquid ammonia at −40° C. The boron–nitrogen stretching frequency has been identified unambiguously as a well-polarized band of medium intensity at 785 cm.$^{-1}$ in ammonia borane ($H_3N : BH_3$). Confirmation of the assignment is found in the results from the isotopic derivatives. As a first approximation, the NH_3 and BH_3 groups may be considered rigid and the ratio of the boron–nitrogen frequencies of two isotopic molecules should then be determined by the reduced masses of the pseudo-diatomic molecules. The appropriate mass ratios based on the hydrogen compound are compared in Table 1 with the frequency ratios observed. In none of the four cases is the deviation greater than about 2 per cent. The simple boron–nitrogen stretching-force constant calculated from the hydrogen compound datum to this approximation is 2·79 × 10^5 dynes/cm.

Table 1. COMPARISON OF THE BORON–NITROGEN STRETCHING FREQUENCY IN ISOTOPIC DERIVATIVES OF AMMONIA BORANE

Compound	ν (B–N)	ν^*/ν	$\sqrt{\mu/\mu^*}$
	(cm.$^{-1}$)		
$H_3N : BH_3$	785	—	—
$H_3N : BD_3$	737	0·94	0·95
$D_3N : BH_3$	754	0·96	0·97
$D_3N : BD_3$	708	0·90	0·91
$D_3N : B^{10}D_3$	713	0·91	0·93

In the case of the methyl amine derivatives, the band in question appeared with approximately the same intensity and depolarization characteristics but with decreasing frequency as the number of methyl groups on the nitrogen increased (Fig. 1). Examination of the trimethylamine complex prepared using boron-10 in 96 per cent enrichment showed the assigned band at 667 cm.$^{-1}$ in the normal compound shifted to 676 cm.$^{-1}$ in the isotopic, whereas the previously assigned[4] band near 1,250 cm.$^{-1}$ was found to shift only 2 cm.$^{-1}$, an amount nearly within the precision of the measurements. The earlier assignment thus appears doubtful, particularly since the 1,250 cm.$^{-1}$ band is weak in the Raman effect.

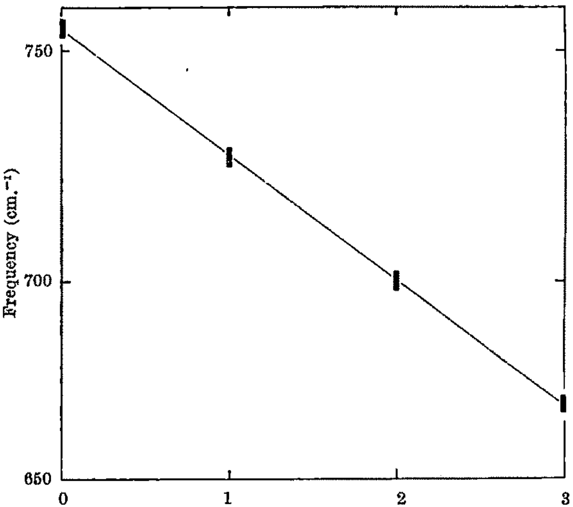

Fig. 1. The vibrational stretching frequency associated with the boron–nitrogen dative bond in some amine boranes

The spectral range within which the boron–nitrogen frequency was found in the present investigation is in good agreement with the frequencies available for other dative bonds to boron in complexes of borane with ligands such as carbon monoxide, phosphorus trifluoride and dimethyl ether.

A more complete presentation of the results will be published elsewhere. This research was supported by the Aeronautical Research Laboratory, Wright Air Development Center, Air Research and Development Command, U.S. Air Force, Wright-Patterson Air Force Base, Ohio.

Molecular Structure of *cyclo*-Octatetraene

AN investigation of the nuclear magnetic resonance absorption spectrum of solid *cyclo*-octatetraene has been made with the object of obtaining information about its molecular structure. Previous determinations of the molecular structure of *cyclo*-octatetraene have used the techniques of infra-red and Raman spectroscopy, and of electron diffraction. The results have been explained in terms of three different molecular models: (1) the 'crown' (D_4) structure with alternate double and single bonds[1]; (2) the 'crown' (D_{4d}) structure with equivalent bonds[2]; (3) the 'tub' (D_{2d}) structure with double and single bonds[3]. Subsequent investigations have supported one or other of these models, but with no real agreement as to which is the most likely structure. Theoretical predictions of the vibrational spectra and diffraction patterns of these three molecular configurations show little difference.

In certain cases, information obtained from a study of the nuclear magnetic resonance absorption spectrum can give valuable information distinguishing between various proposed molecular models. Accordingly the second moment of the proton resonance absorption line was measured at a temperature close to the melting point. The mean value obtained was 7·9 ± 0·2 gauss^2. This has to be compared with the theoretical values calculated for each of the three different configurations. The expected second moment was also calculated for the simple planar model with equivalent bonds, although the above results showed that this was a very unlikely possibility. The results are shown in Table 1.

The C—C and C=C bonds were taken as 1·54 A. and 1·34 A. respectively. The equivalent C—C bond was taken as 1·42 A., being 2 per cent greater than the corresponding bond-length in benzene, as suggested by Bastiansen *et al.*[2]. The D_4 and D_{2d} structures were assumed to have angles of 125° between the carbon bonds, the D_{4d} structure 120° between these bonds and the plane molecule, being in the form of a regular octagon, angles of 135° between the carbon bonds. The C—H bond-length was taken as 1·07 A. for the D_4 and D_{2d} structures and as 1·08 A. for the D_{4d} and planar structures. The intermolecular contribution to the second moment (due to interactions between protons in different molecules) was calculated on the basis of the orthorhombic crystal structure found by Kaufman, Fankuchen and Mark[4], with reasonable assumptions regarding the orientation of the molecules in the cell.

Table 1

Molecular structure	Second moment of absorption lineshape in gauss^2		
	Intramolecular	Intermolecular	Total
D_4	2·38	7·75	10·13
D_{4d}	1·99	7·05	9·04
D_{2d}	2·99	5·00	7·99
Plane	5·75	5·47	11·22

Comparison of the experimental and theoretical values for the second moment indicates that the 'tub' D_{2d} structure is the most probable one for *cyclo*-octatetraene. The D_{4d} structure gives a second moment which is more than 1 gauss^2 too large, but it must be mentioned that the intermolecular contribution to this second moment amounts to 78 per cent of the total. This is the least accurate part of the calculation because of the assumption made regarding the orientation of the molecule in the unit cell. There is, therefore, some uncertainty in the value 7·05 gauss^2 for the intermolecular part of the second moment, but it is not thought to be so large as to reduce this value by as much as 1 gauss^2.

The D_{2d} structure for *cyclo*-octatetraene has recently been confirmed using highly refined electron diffraction techniques by Bastiansen, Hedberg and Hedberg[5], reported after the completion of the present work.

The *cyclo*-octatetraene was kindly supplied by the British Oxygen Research and Development, Limited.

Use of Molecular Sieves in Gas Chromatography for the Determination of the Normal Paraffins in Petroleum Fractions

THE use of Linde molecular sieve 5*A* in conjunction with gas chromatography[1–3] offers considerable promise as a means of determining *n*-paraffins in hydrocarbon mixtures. Recently, Brenner and Coates[4] reported the application of this technique to the identification of *n*-paraffins in the C_3 to C_{11} (gasoline) range. We have successfully used it in a higher molecular weight range, namely, for the determination of the *n*-paraffin content and distribution in kerosines and gas oils. Since this may also be of general interest our method will be outlined here.

The saturated fraction of the kerosine or gas oil was separated by liquid–solid chromatography and a portion run through a 2-metre gas chromatographic column packed with 30–60 mesh 'Sil-o-cel' firebrick coated with 26 per cent by weight of silicone grease *E* 301 (Imperial Chemical Industries). The type of chromatogram obtained for a kerosine fraction at a column temperature of 164° C. is shown in Fig. 1*a*. The normal paraffin peaks have been shaded to show how they are superimposed upon and only partially separated from the other saturated hydrocarbons. A pre-column of 11 cm. length packed with 30–60 mesh Linde molecular sieve 5*A* coated with 1·6 per cent by weight of squalane, to prevent tailing effects, was now attached to the main column and maintained at 150° C. A further similar portion of the saturated fraction of the kerosine was run through this dual column and a second chromatogram obtained (Fig. 1*b*) free from the normal paraffins which were retained by the molecular sieve. The difference in area between the two chromatograms was a measure of the normal paraffin content, and the amount of each individual normal paraffin was similarly obtained from the difference in peak area at the respective normal paraffin elution times on the two chromatograms when using hydrogen as the carrier gas with a thermal conductivity detector. Typical results obtained are shown in Table 1 and the total normal paraffin contents are compared with those obtained by a liquid phase separation with molecular sieves.

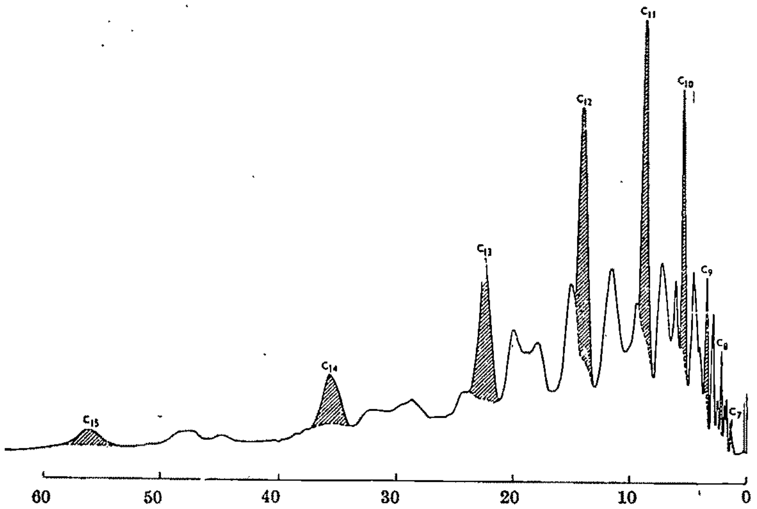

Fig. 1*a*. Chromatogram of a kerosine saturated fraction showing the *n*-paraffin peaks. Sample size, 13 µl.; column, 200 cm. × 6 mm. internal diameter, 26 per cent silicone grease *E*301 on 30–60 mesh 'Sil-o-cel' furnace brick; column temperature, 164° C.; katharometer temperature, 170° C.; carrier gas, hydrogen; outlet pressure, atmospheric

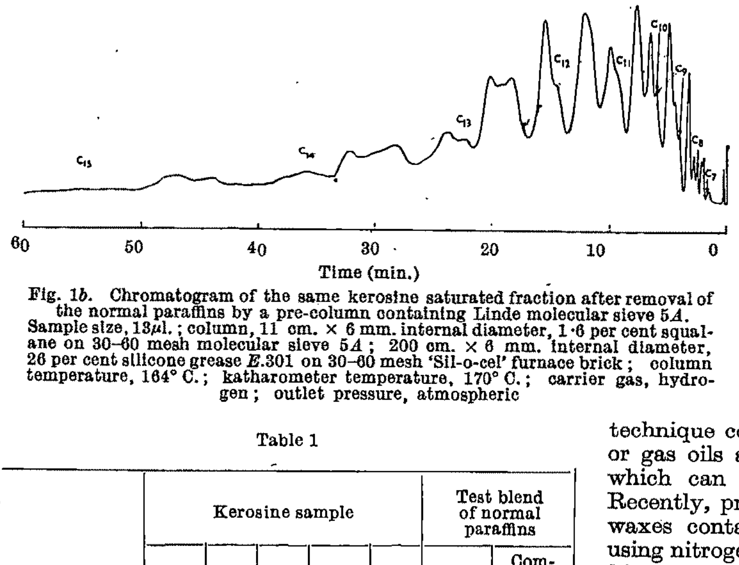

Fig. 1*b*. Chromatogram of the same kerosine saturated fraction after removal of the normal paraffins by a pre-column containing Linde molecular sieve 5*A*. Sample size, 13µl.; column, 11 cm. × 6 mm. internal diameter, 1·6 per cent squalane on 30–60 mesh molecular sieve 5*A*; 200 cm. × 6 mm. internal diameter, 26 per cent silicone grease *E*.301 on 30–60 mesh 'Sil-o-cel' furnace brick; column temperature, 164° C.; katharometer temperature, 170° C.; carrier gas, hydrogen; outlet pressure, atmospheric

Table 1

Percentage by volume	Kerosine sample					Test blend of normal paraffins	
	1	2	3	4	5	Actual composition	Composition from gas-liquid chromatography
Total *n*-paraffin by molecular sieve (liquid phase)	22	27	26	11	9		
Total *n*-paraffin by molecular sieve (gas phase)	23	31	26	12	8		
Individual *n*-paraffins							
C_7	Trace	—	—	Trace	—	—	—
C_8	1·0	0·6	0·2	0·1	0·8	—	—
C_9	4·9	3·6	0·6	0·9	1·8	3·1	3·4
C_{10}	5·3	9·2	1·8	2·3	1·7	7·7	8·3
C_{11}	4·8	8·4	6·5	2·4	1·5	22·6	22·5
C_{12}	3·9	6·2	5·5	2·2	1·1	29·8	29·7
C_{13}	1·9	2·3	4·8	1·9	0·7	22·2	22·5
C_{14}	0·9	0·5	4·0	1·3	0·4	14·6	13·6
C_{15}	0·3	0·2	1·9	0·6	—	—	—
C_{16}	—	—	0·7	0·3	—	—	—

The molecular sieve pre-columns have retained their capacity to adsorb the normal paraffins from at least 30 kerosine samples representing approximately 85 mgm. of adsorbate. It seems that the same technique could be applied to the original kerosines or gas oils and indeed to any hydrocarbon mixture which can be separated by gas chromatography. Recently, promising results have been obtained with waxes containing normal paraffins as high as C_{40} using nitrogen carrier gas and a 0·6 m. column with a 10 cm. pre-column containing the molecular sieve. As squalane could not be used to reduce tailing at high temperatures it was found that this effect could be eliminated by maintaining the pre-column at a temperature of 320° C. while the main column was operating at temperatures in the range 270–300° C.

I wish to thank the Directors of Shell Research Ltd., for permission to publish this communication, and Miss P. M. Higham and Mr. J. B. Shortall, who have taken part in the work described.

Swift Combustion of Organic Compounds for Analysis

A NOVEL apparatus has been designed for rapid combustion of organic compounds, including volatile ones, for analysis (Fig. 1). A closed system is used, as by Mikl and Pecht[1], and Schöniger[2 3], while retaining platinum contacts as used by Pregl[4] and the usual method of taking samples.

The apparatus (patent applied for by Loughborough Glass Co., Ltd., Loughborough) consists of a quartz bulb *V*, equipped with a *B*24 joint opposite a combustion U-tube *CT*, the limbs of which are sufficiently close together to allow heating by a single flame. The flask is connected via joint *B*24 to syphon tube *T* in reservoir *R*, which can be closed with stopper *B*19 in a socket extended into a funnel *F*.

To carry out the combustion, the apparatus is flushed with oxygen. A sample between 3 and 7 mgm. is weighed, solids in boats and liquids in capillaries. The sample in its container is placed in a glass tube, one end of which is held against one orifice of tube *CT*, while the container is pushed forward with a glass rod. Capillaries are placed in tube *CT* with the open end forward. Volatile compounds are cooled by placing solid carbon dioxide externally over the sample. In the same way contacts *C* are inserted on both sides of tube *CT*. Reservoir *R* is half-filled with absorption solution, and attached to bulb *V*, a wetted 'Teflon' sleeve *TS* being slipped over the stopper, which is held by springs. Two asbestos sheets, *Asb*, are arranged over combustion tube *CT*. The platinum contacts *C* are then heated by burner *B*. Excess oxygen will escape freely through the absorption solution. When burning volatile compounds, solid carbon dioxide is kept over the sample until the contacts are glowing. Then reservoir *R* is closed with stopper *B*19, and combustion of the compound carefully started using a microburner. The rate of volatilizing can be assessed by the speed of bubbles escaping tube *T*. Combustion is completed by heating the whole length of tube *CT* with a second burner. The apparatus is left to cool, or cooled rapidly using a damp cloth. Funnel *F* is filled with distilled water and stopper *B*19 carefully lifted until the water is sucked in. The contents are shaken. Funnel *F* is filled again with distilled water and this procedure repeated four times. The absorption tube and contacts are removed, rinsed quantitatively, and the contents of the flask transferred to a container according to the analysis required. Many methods described in the literature will be found suitable for the determination of halogens and sulphur in that solution.

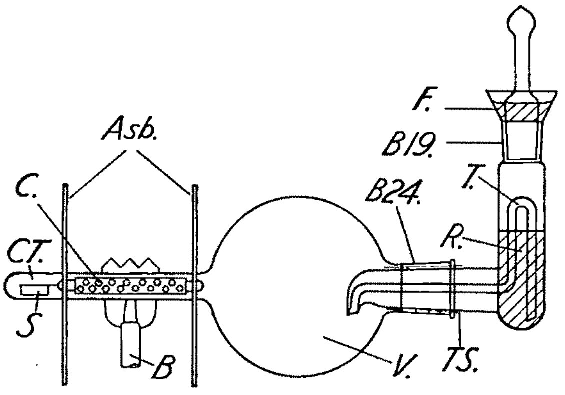

Fig. 1

Table 1

Compound	Sample (mgm.)	Percentage chlorine	
		Calc.	Found
Carbon tetrachloride	3·230	92·19	92·23
	3·600		92·26
	3·662		91·79

Some Complex Cyanides of Rhenium

SEVERAL attempts have been made to prepare complex rhenium cyanides, but invariably these have resulted in mixed compounds. For example, in 1932 Turkiewicz[1] obtained $K_3[ReO(CN)_4OH]$, and later Morgan[2] prepared $K_3[ReO(CN)_4]$; Klemm and Frischmuth[3] and Morgan and Davis[4] described the preparation of $K_3[ReO_2(CN)_4]$. A rhenium carbonyl cyanide anion $[Re(CO)_4(CN)_2]^-$ was reported by Hieber and Schuster[5]. The only evidence in the literature for the existence of a true complex rhenium cyanide comes from polarographic studies[6,7].

We report the preparation of the binary complex rhenium octacyanides, potassium octacyanorhenate-V, $K_3Re(CN)_8$, and potassium octacyanorhenate-VI, $K_2Re(CN)_8$. With the exception of the well-known molybdenum and tungsten compounds, these are the only eight-co-ordinate cyanides, so far reported, and the first eight-co-ordinate rhenium compounds.

When potassium hexa-iodorhenate-IV, K_2ReI_6, is added to potassium cyanide in methanol, the octacyanorhenate-V is formed as a brown precipitate. Found: Re, 34·4; K, 21·9; C, 18·6; H_2O, 3·3. Required for $K_3Re(CN)_8 \cdot 1H_2O$: Re, 35·1; K, 22·1; C, 18·1; H_2O, 3·4.

Potassium octacyanorhenate-V dissolves in water to give a stable yellowish-brown solution which yields the free acid when passed through an ion exchange column.

When concentrated nitric acid is added to potassium octacyanorhenate-V solution, a reddish product can be isolated which shows a peak in its infra-red spectrum at 1,875 cm.$^{-1}$, a value which is assigned to the NO stretching frequency. Treatment of potassium octacyanorhenate-V solution with concentrated hydrochloric acid yields a purple solution. A potassium salt cannot be isolated from this solution, but addition of hexamine cobaltic chloride gives an insoluble purple precipitate which is hexammine cobaltic octacyanorhenate-VI, $[\mathrm{Co(NH_3)_6}]_2[\mathrm{Re(CN)_8}]_3$, the cobalt hexammine salt of the $[\mathrm{Re(CN)_8}]^{=}$ ion. Found : Co, 7·8 ; Re, 36·0. Required for $[\mathrm{Co(NH_3)_6}]_2$ $[\mathrm{Re(CN)_8}]_3$: Co, 7·8 ; Re, 36·5.

The infra-red spectrum of potassium octacyanorhenate-V in 'Nujol' mull shows three cyanide-stretching frequencies at 2,140 cm.$^{-1}$, 2,110 cm.$^{-1}$ and 2,050 cm.$^{-1}$, very similar to the infra-red spectra of the molybdenum and tungsten octacyanides[8]. The spectrum also shows a sharp peak at 780 cm.$^{-1}$, which may be either a Re—C stretching mode or a C≡N wagging mode.

Potassium octacyanorhenate-V is diamagnetic. The oxidation from rhenium-IV to rhenium-V during the preparation is of some interest. Considering an octa-co-ordinate cyanide complex for rhenium-IV, of the three *d*-electrons two may enter the non-bonding stable 5*d*-orbital which is unused in σ-bonding ; the third, however, would have to enter a high-energy orbital, most likely one of the anti-bonding σ-orbitals, from which it is readily lost.

The hexammine cobaltic salt of the octacyanorhenate-VI ion is paramagnetic with a magnetic moment of 2·0 Bohr magnetons.

A detailed account of this work will be published elsewhere.

Moving Acid Boundary (*p*H Gradient) Paper Ionophoresis of Bile Salts

Methods have been devised for the separation of bile acids and their conjugates with glycine or taurine using partition chromatography on columns[1,2] or paper[3,4]. These methods, however, may confuse certain glycine conjugated acids with the unconjugated bile acids containing a greater number of hydroxyl groups[4]. Thus ambiguous separations may result if unconjugated bile acids are also present in the mixture.

Free[5,6] and paper[7] electrophoresis with a stationary *p*H gradient has been used to separate proteins on the basis of differences in their isoelectric points. We have applied ionophoresis with a moving acid front to separate bile salt mixtures utilizing the differences in acid dissociation constants. (The pK_a's of taurocholic, glycocholic and cholic acids are respectively 1·4, 4·4 and 6·4). With this method, using a standard paper ionophoresis apparatus, a bile salt mixture can be separated into three groups : unconjugated bile acids, glycine conjugates and taurine conjugates.

The cathode compartment contains 0·05 *M* acetate buffer, *p*H 4·8 and 0·03 *M* sodium chloride. The anode compartment contains 0·05 *M* monochloroacetate buffer, *p*H 2·7, and 0·03 *M* sodium chloride. Up to 500 μgm. of the bile salt mixture is applied to a strip of Whatman No. 3 paper (6·5 cm. × 46 cm.), 15 cm. from one end. The paper is impregnated with acetate buffer and placed in the ionophoresis apparatus with the point of application nearest the cathode chamber. The separation is carried out for 16 hr. under a potential gradient of 5 V./cm.

Initially at *p*H 4·8, the conjugated bile acids migrate together toward the anode, the weaker unconjugated acids being immobile. As the separation progresses, the simultaneous migration of hydrogen ions from the anode compartment (the advancing acid front) represses the ionization of the glycine conjugates. These are consequently rendered immobile. The taurine conjugates continue to move through the acid front and are found near the anode. The glycine conjugates and the free acids are located near the middle of the paper and origin, respectively. Afterwards each area may be eluted, the substances separated, and identified by appropriate chromatographic procedure.

The presence of buffered salt mixtures in the paper may seriously interfere with the location of the bile acids by the colorimetric reagents commonly employed[8]. A reagent which has been found useful is 3 per cent (w/v) vanillin and 15 per cent (v/v) phosphoric acid in *sec*-butanol.

This method has been used to separate mixtures of pure synthetic conjugated bile acids as well as crude mixtures of natural origin. The presence of unconjugated cholic acid in the latter has been demonstrated.

The application of an effective *p*H gradient during ionophoresis promises to be of much use for the separation of compounds differing in their ionization constants as acids or bases. This method eliminates the necessity of conducting ionophoresis at two or more *p*H's in order to identify, for example, carboxylic acids in the presence of phosphate esters.

Experimental Chemotherapy of Tumours with Hydrogen Peroxide

R. A. Holman has reported[1] that a high percentage of rats bearing Walker carcinoma 256 were cured after drinking hydrogen peroxide instead of water. These findings were not confirmed by Green and Westrop[2], nor by Ghadially and Wiseman[3] using Walker carcinoma 256 and Sheffield *RD*/3 sarcoma in rats. We have repeated Holman's experiment with some transplantable tumours of mice and rats.

Table 1. Animals and Tumours used in the Experiments

Group	Animals	Sex	Strain	Tumours	No. of animals fed: hydrogen peroxide	No. of animals fed: distilled water
I	Mice	*F*	*Br**	Transplantable solid carcinoma of the breast (G_4)	25	25
II	Mice	*F*	*A*	Transplantable adenocarcinoma of the breast (G_{44})	10	6
III	Mice	*F*	*Br**	Crocker sarcoma	15	15
IV	Mice	*F*	Hybrids	Ehrlich ascites carcinoma	14	14
V	Rats	*F*	Wistar	Guerin carcinoma	8	8
	Rats	*M*	Wistar	Guerin carcinoma	8	8

* Inbred strains from our animal colony.

One group of animals was given commercial hydrogen peroxide (diluted to final concentration of 0·45 per cent in distilled water) to drink; the other received distilled water. Both hydrogen peroxide and distilled water were supplied in dark bottles refilled every day. Both groups of animals received the standard diet used in our animal colony.

In groups I, II, III and V (Table 1), treatment with hydrogen peroxide was started 7, 3, 14 and 19 days respectively after implantation of grafts. In group IV (Ehrlich ascites carcinoma) treatment with hydrogen peroxide was started the day after transplantation.

The rate of growth of the solid tumours was expressed as a mean diameter, measurements of tumours being made two or three times a week, using Schrek's technique[4] as modified in our laboratory. In the case of Ehrlich carcinoma both groups of mice were weighed daily. In all cases the time of survival of the animals was noted.

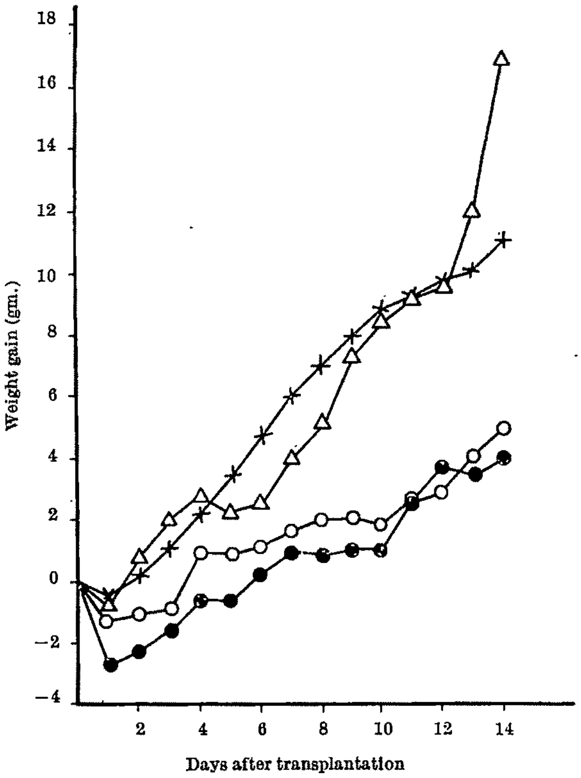

Fig. 2. Ehrlich ascites sarcoma: gain in weight of mice on hydrogen peroxide compared with those on distilled water. Experiments performed on two groups of animals: group (*a*) had an average initial weight about 25 gm., group (*b*) about 18 gm. —●—, (*a*) and —○—, (*b*), hydrogen peroxide-treated; —△—, (*a*), and —×—, (*b*), distilled water-treated

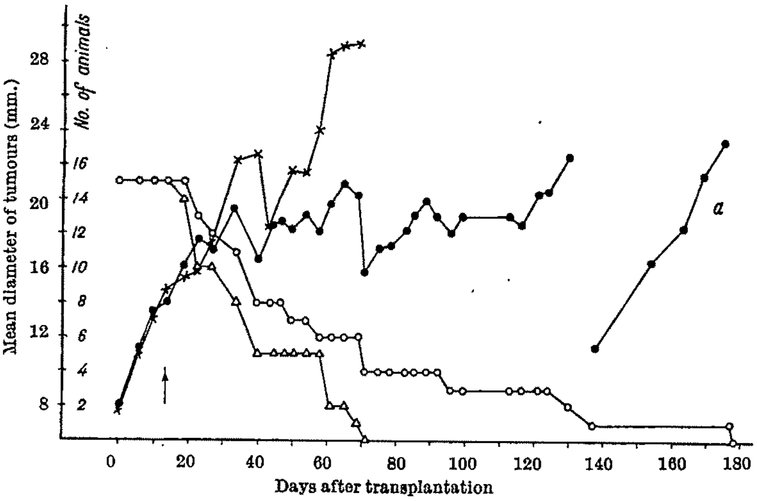

Fig. 1. Crocker sarcoma: survival time of mice receiving hydrogen peroxide (—○—) and distilled water (—△—). Rate of growth of tumours of hydrogen peroxide-treated (—●—) and control (—×—) animals; size of tumours expressed as mean diameter of tumour, averaged from tumours of animals living on a given day. The arrow indicates the start of treatment with hydrogen peroxide. Curve *a*, rate of growth of tumour in the single mouse surviving

No significant effect of hydrogen peroxide on the rate of growth of tumours or on survival-time was observed in groups I, II and V. The results obtained with groups III and IV are illustrated in Figs. 1, 2 and 3.

As can be seen from Fig. 1, the rate of growth of Crocker sarcoma in mice fed on hydrogen peroxide was somewhat slower than in the control group. The regression of tumours in the treated group was not observed; however, the growth of some tumours became stationary. The effect was responsible for the prolongation of survival-time in these animals (Fig. 1). When the 'stationary period' ended, the rate of growth of the tumours of treated animals was almost as great as in control ones. This is well illustrated by the rate of growth of a tumour in the mouse which had the longest survival time (Fig. 1,*a*).

The rate of growth of Ehrlich ascites carcinoma, as expressed by the gain in weight of the animals, was diminished in the group treated with

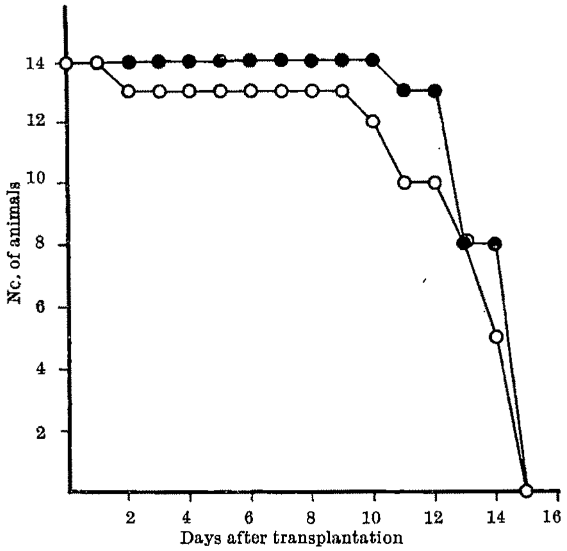

Fig. 3. Ehrlich ascites sarcoma: survival time of hydrogen peroxide-treated (—●—) and control (—○—) mice

hydrogen peroxide (Fig. 2), yet the treatment had no influence on the survival time of these mice (Fig. 3).

From this work it is not possible to assess the activity of hydrogen peroxide *per se* against tumour growth, because of some uncontrolled experimental conditions. In particular, the intake of food and water must be taken into consideration. We noticed that the intake of hydrogen peroxide solution by treated animals was much smaller than the intake of distilled water by control animals. Diminished food intake followed by loss of weight in healthy rats drinking hydrogen peroxide as compared with rats supplied with tap water was observed by Ghadially and Wiseman[3]. It seems very probable that changes in nutritional conditions brought about by drinking hydrogen peroxide (diminished food intake, or direct action of hydrogen peroxide on some essential constituents of ingested food) may be causal factors sometimes mediating an inhibitory effect on certain kinds of tumours.

Anticholesterol Activity of α-Lipoic Acid

A recent report in *Nature*[1] concerning the 'anticholesterol' properties of α-lipoic acid has prompted communication of similar experiments in which different results were obtained.

In our work two groups of male Dutch belted rabbits (*A* and *B*) were maintained on a diet containing 2 per cent cholesterol and 6 per cent corn oil for two months. A third group (*C*) was kept as a normal control. One of these groups (*B*) also received daily intraperitoneal injections of 1 mgm. of α-lipoic acid, which represented 0·5–1 mgm./kgm. body-weight for the animals used. After eight weeks the animals were killed, the sera assayed chemically for cholesterol[2] and ultracentrifugally for β-lipoproteins[3] and the aortas graded visually (on a 0–4 scale) for atheromata. The results are shown in Table 1.

Table 1. Autopsy Results for Rabbits fed with Cholesterol

Group	No.	Atheromata (average) Arch	Thoracic	Liver weight (gm.)	Gain in weight (gm.)
A	10	2·10	1·25	93	219
B	10	2·50	1·65	90	49
C	5	0·00	0·10	63	449

Table 2. Serum of Rabbits fed with Cholesterol

Group	Average cholesterol (mgm./100 ml.)	Average lipoproteins (mgm./100 ml.) *Sf* 0–11	12–20	21–35	35–100	100–400
A	1,893	220	517	839	997	663
B	1,853	263	731	1,015	782	443
C	175	146	75	43	30	25

The most obvious source of discrepancy is the fact that Angelucci and Mascitelli-Coreandoli[1] administered considerably more α-lipoic acid than we did. In the absence of weights of the animals, it cannot be said if their rabbits showed even less weight gain than ours did. It is also worth noting that whereas their lipoic-acid group showed 20 per cent of the serum cholesterol-levels of the cholesterol-fed controls, they showed 66 per cent of the aorta cholesterol. In our work there was increased atherosclerosis in the lipoic acid group.

These results, indicating one of the lower limits at which no effect of α-lipoic is discernible, may serve as a guide in defining dosages, and may stimulate further work.

David Kritchevsky

[3] Gofman, J. W., Lindgren, F., Elliott, H., Mantz, W., Hewitt, J., Strisower, B., Herring, V., and Lyon, T. P., *Science*, **111**, 166 (1950).

The discrepancy between our results and those of Kritchevsky and Moyer could be explained as follows:

(*a*) In comparison with the dosages used by Kritchevsky and Moyer, our rabbits were given a smaller total amount of cholesterol and a greater total amount of α-lipoic acid, with a ratio between cholesterol and α-lipoic acid comparatively in favour of the latter in unit time.

(*b*) That there is a critical value in the α-lipoic acid dosage for the 'anticholesterol properties' can be argued from the fact that in humans with high serum cholesterol-levels, chronic treatment with α-lipoic acid 25 mgm. twice a day did not change the serum cholesterol-levels, whereas 50 mgm. once a day gave a moderate decrease in the serum cholesterol levels (Consolo *et al.*, *Boll. Soc. Ital. Biol. Sper.*, 32, 1325; 1957).

Existence and Significance of a Physiological Anticoagulating System

When moderate doses of tissue thromboplastin are injected into the jugular vein of rats the circulating blood loses its clotting properties, with the result that no intravascular thrombi are, as a rule, produced. This effect of thromboplastin depends upon its capacity for inducing the formation of thrombin in blood from the plasma prothrombin. In most cases intravenous administration of moderate doses of thrombin to healthy animals does not cause thrombosis, for the clotting mechanism becomes disordered almost immediately after the injections. At the same time the thromboplastic activity of blood shows a sharp decrease, while fibrinogen capable of reacting with thrombin disappears and heparin-like substances appear in the blood. This protective reaction, maintaining the blood in a fluid state in the vascular bed when thrombin arises in it, is brought about by the physiological anticoagulating system. Experiments have shown that in narcotic sleep resulting from inhalation of sulphuric ether, as well as from anæsthesia produced by an intramuscular injection of novocaine on both sides of the spinal column, this anticoagulating system ceases to function. It is this effect that accounts for the fact that coagulation of circulating blood and death from thrombosis have been found to occur in anæsthetized test animals (as opposed to controls in a normal physiological condition) after an intravenous administration of certain doses of thrombin (Table 1).

It thus appears possible that there may exist certain receptors in the blood vessels which react to the presence of thrombin and actuate the neuro-humoral mechanism, preventing coagulation of the blood circulating in the vessels. There is no doubt that pathological changes in the vessel walls as well as impairment of circulation may lead to the formation of thrombin in the vascular bed. Whereas with an anticoagulating system functioning normally, the coagulation of the circulating blood is to a certain extent avoided, in any disturbance of that system the appearance of thrombin in the circulating blood, whatever its cause may be, can give rise to the formation of clots.

It is probable that the anticoagulating system partly loses its function as a result of changes in the body with age and of toxic effects occurring in case of some infectious diseases, as well as in narcosis or anæsthesia (post-operative thrombosis). The latter fact is proved experimentally. It is possible that in the normal physiology of blood a restricted formation of thrombin in the vascular bed is constantly taking place, but the blood does not clot owing to the action of the physiological anticoagulating system.

In cases of disturbance of the anticoagulating system, even with decreased prothrombin content in the blood and its slower conversion to thrombin, the possibility of the formation of thrombin still remains, a fact which does not exclude the conversion of fibrinogen to fibrin in the vascular bed.

On the basis of this hypothesis, the problem of thromboses should be approached not from the point of view of an excess of coagulating components in the circulating blood or the pathology of the vessel wall but through an analysis of the physiological state of the anticoagulating system present outside the vascular bed.

Table 1. Inhibition of the Anticoagulating System under the Influence of Ether or Novocaine Anæsthesia

No. of animals	Activity of thrombin (sec.)*	Dose of intravenous thrombin (ml.)	Experimental conditions	No. of animals surviving	No. of animals dead from thrombosis
30	6	0·5	Animals anæsthetized with ether after 15 min. sleep	5	25
30	6	0·5	Control animals in normal physiological state	26	4
30	6	1·0	Control animals anæsthetized with ether after 15 min. sleep. Thrombin fully inactivated by heating for 6 min at 57° C.	30	0
30	6	0·5	Animals given intramuscular injections of novocaine along spinal column	11	19
30	6	0·5	Control animals in normal physiological state	26	4
30	6	0·5	Control animals given intramuscular injections of novocaine along spinal column. Thrombin fully inactivated by heating for 6 min. at 57° C.	27	3

* Thrombin solution clotted an equal volume of oxalated blood in 6 sec. at 37° C.

Carbohydrate Metabolism of Cock Spermatozoa

Glycolysis in spermatozoa of mammalian species has been much studied. These investigations, extensively reviewed by Mann[1], have demonstrated that mammalian spermatozoa utilize fructose, glucose and mannose; anaerobically, they degrade these sugars to lactic acid, deriving from this process the energy necessary for motility.

Winberg[2] demonstrated that cock spermatozoa produce lactic acid by aerobic glycolysis of glucose, fructose or mannose, and that these sugars (and also maltose to a slight extent) support their respiration, but to my knowledge glycolysis in avian spermatozoa has not been further studied systematically. This communication reports the results of an investigation on the carbohydrate metabolism of spermatozoa of the domestic cock (*Gallus domesticus*).

Semen collected from Rhode Island Red cocks by the abdominal massage method of Burrows and Quinn[3] was diluted, within 20 min. of collection, with the pre-warmed appropriate medium, and then, after removing an aliquot for initial analysis, was incubated in a water-bath at 40° C. The incubation was carried out in two ways: (1) in stoppered, 7–75-mm. test tubes containing 1–2 ml. of the mixture, which were left undisturbed in the bath, thus providing semi-anaerobic conditions, and (2) in Warburg flasks containing 2 ml. of the mixture and attached to manometers which were shaken, thus providing aerobic conditions. Most experiments were performed in a buffered avian Ringer phosphate, pH 7·4 (containing NaCl 0·97, $MgSO_4.7H_2O$ 0·025, $NaHCO_3$ 0·10, $NaHPO_4$ 0·1984 and KH_2PO_4 0·1815 per cent). All experiments were performed in mixtures of 3 parts diluent to 1 part of either whole semen or washed sperm resuspended to the original concentration. Total reducing substances in the mixtures were determined by the method of Hagedorn and Jensen[4] and fructose by the resorcinol method of Roe[5] as adapted to semen by Mann[6] in protein-free filtrates obtained by using barium hydroxide and zinc sulphate.

Although cock semen is notoriously poor in fructose[1], mixtures of cock semen and Ringer phosphate to which fructose was added in a concentration of 3·0 mgm. per ml. utilized fructose at the rate of 0·63–0·76 mgm. per 10^9 sperm during the first hour under semi-anaerobic conditions. Aerobically, 0·42–0·55 mgm. fructose was utilized by 10^9 sperm during the same period. Curves of utilization of fructose were not linear, presumably due to progressive inactivation of incubated spermatozoa and gradual depletion of the substrate. For example, in mixtures containing about $1{\cdot}5 \times 10^9$ sperm per ml. an average of 39 per cent of fructose was utilized during the first hour, 21 per cent during the second and a further 18 per cent during the third hour.

In order to determine whether cock spermatozoa, like those of bull and ram, utilize aldoses preferentially to fructose, cock spermatozoa were incubated in mixtures containing 3 mgm. fructose plus 6 mgm. of either glucose or mannose per ml. Surprisingly, in these mixtures no decrease in fructose whatever could be observed, and, in fact, the fructose content appeared to increase slightly. In a subsequent series of incubations carried out in diluents containing either glucose or mannose as the sole sugar, a definite accumulation of fructose was readily demonstrable. A typical experiment is illustrated in Fig. 1. In this experiment a 1 : 3 mixture of cock semen and Ringer phosphate, supplemented with 3 mgm. glucose per ml., during 3 hr. aerobic incubation at 40° C. produced 0·98 mgm. fructose per ml., which represents a conversion of more than 30 per cent of glucose into fructose. At the end of incubation the mixture contained more than twice as much fructose as glucose. The identity of fructose was confirmed by the yeast-fermentation test.

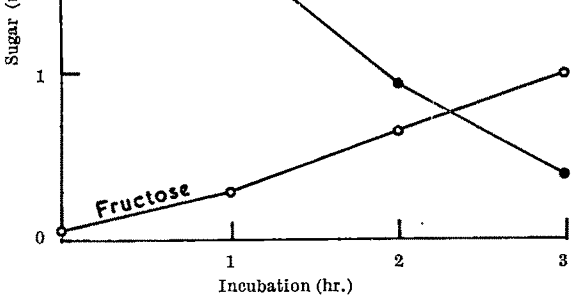

Fig. 1. Glucose utilization and fructose formation by diluted cock semen during aerobic incubation at 40° C.

Under the experimental conditions referred to in Fig. 1 the rate of formation of fructose was found to be approximately twice as high in aerobic as in anaerobic conditions. It was also found to be fairly independent of the initial concentration of aldose, at least over a certain range. When, however, the initial concentration of aldose was very small the rate of accumulation of fructose was much smaller. An average of 0·17 mgm. of fructose accumulated during the first hour in the presence of 2–6 mgm. aldose, but when the initial supply was limited to 0·8 mgm., only 0·06 mgm. fructose accumulated during the first hour and most of this disappeared during the second.

The formation of fructose in cock semen supplemented with glucose was found to be dependent on the presence of live spermatozoa. It was also demonstrated in suspensions of washed but motile spermatozoa. A pooled sample of semen was centrifuged, the packed cells suspended in Ringer phosphate, the suspension divided into two equal portions and both portions centrifuged. One portion was resuspended in half the original volume of seminal plasma and the other in the corresponding volume of Ringer phosphate. Samples of each were incubated with glucose and with mannose, each sugar at an initial concentration of 3 mgm. per ml. During the first hour 0·20 mgm. fructose was formed from either glucose or mannose in the presence of seminal plasma and 0·21 mgm. in the presence of Ringer phosphate ; after 3 hr., respectively 0·75 and 0·68 mgm. fructose had accumulated.

Since cock spermatozoa convert glucose and mannose to fructose the question arises whether they are also able to carry out the reverse reaction. The existence of such a reverse reaction could not be demonstrated, at least under aerobic conditions. In cock semen incubated for 3 hr. with 3 mgm. fructose per ml. 0·98 mgm fructose disappeared while the level of reducing substances other than fructose declined from 0·47 to 0·20 mgm. per ml. Under semi-anaerobic conditions the results were less clear. Here small but irregular amounts of non-fructose reducing material accumulated, but much of it proved to be non-fermentable by yeast.

This investigation was conducted during my tenure of a National Science Foundation Fellowship while on sabbatical leave from the University of California, Davis, California. The cordial and invaluable interest and advice of Dr. T. Mann throughout the investigation are gratefully acknowledged.

Distribution of Newly Synthesized Deoxyribonucleic Acid in Mitotic Division

Firket and Verly recently presented[1] some results on the labelling of chromosomal deoxyribonucleic acid in chick fibroblast cells with tritiated thymidine. One of their conclusions is that their results support the hypothesis of the equal distribution of labelled, and hence newly synthesized, deoxyribonucleic acid between sister anaphase and telophase chromosome sets and contradict an earlier observation by Mazia and me[2] that this distribution may be decidedly unequal.

An inequality which exceeds that to be expected from the random distribution of the products of replication of different chromosomes and from the random distribution of decaying isotopic atoms suggests that there is an additional variant: a daughter chromosome may differ from its sister in the amount of newly synthesized deoxyribonucleic acid; in other words, the formation of daughter chromosomes from the maternal complex involves the random assortment of a small number of new and old units of deoxyribonucleic acid. This was the conclusion reached by us from an analysis which involved a mitotic system of six chromosomes and thymidine-^{14}C as the deoxyribonucleic acid marker[2].

A more direct approach to the problem was carried out by Taylor *et al.*[3]: tritiated thymidine was substituted for thymidine-^{14}C, thus permitting the autoradiographic analysis of single pairs of sister chromosomes rather than whole sets. Their conclusion was that sister chromosomes always shared equally in the deoxyribonucleic acid most recently synthesized, that the formation of daughter chromosomes did not involve the random assortment of the new and old structural units of the deoxyribonucleic acid of the mother complex. More recent experiments of mine strongly suggest, however, that these latter results are rather more complex than first appeared, that they are subject to a different interpretation from that offered by Taylor *et al.*[3], and that they by no means exclude the earlier conclusion of random assortment. In short, the question of the mode by which the mother chromosome is transformed into its two daughters is still unresolved and in need of further experimental elucidation.

The study of Firket and Verly[1] has a direct bearing on this question: if significant anaphase and telophase inequality of newly synthesized deoxyribonucleic acid is ruled out, then an equal partition of the material between daughter chromosomes is indicated. I should like to point out, however, that the experimental system chosen by these authors makes it virtually impossible to arrive at any significant quantitative conclusions. Unlike the experiment of Taylor *et al.*[3], the study by Firket and Verly looks at whole sets of post-metaphase chromosomes. In this respect it resembles our earlier investigation of the six-chromosome system (*Crepis capillaris*). In sharp contrast with the latter, however, the chick fibroblast cell presents a very difficult statistical problem indeed: with upwards of 60 chromosomes the number of cells that must be analysed in order to separate the random inequalities introduced by the independent behaviour of different chromosomes from those which might be introduced by the segregation of chromosomal sub-units is extremely large. Similarly, the number of grains in the autoradiographic image should be large enough to permit the statistical separation of random distribution and decay errors from biologically significant inequality. The actual results on which Firket and Verly base their conclusion[4] suggest that neither of these conditions is fulfilled. The number of cells analysed is 19, the average number of silver grains in the emulsion per cell is 47. In such a sample of a mitotic distribution system with 60 or more chromosomes one cannot hope to detect inequalities which are ascribable to differential labelling of sister chromosomes. The only conclusion which can be drawn from these results is that newly synthesized deoxyribonucleic acid is distributed between post-metaphase chromosome sets in chick fibroblast cells. The question of the equality or inequality of this distribution remains unelucidated.

[4] Firket, H., *Arch. Biol.*, **69**, 1 (1958).

I AGREE with Dr. Plaut that my results, though different from his, do not rule out the conclusions arrived at by him and Dr. Mazia. In fact, in the detailed paper[1] to which he refers, I wrote (p. 84): "Même si cette [Dr. Plaut and Mazia's] hypothèse sur la duplication de l'ADN est exacte, une telle déviation n'aurait qu'une chance infime d'apparaître dans les cellules de Poulet où le nombre de chromosomes est beaucoup plus élevé". I doubt the conclusions of their experiments for other reasons: namely, the inaccuracy of the limits of the field to be measured, the various possible errors in the quantitative assessment of radioactivity, and the contrary experiments by Taylor *et al.*[2].

I quite agree, however, that no definite conclusions have yet been reached about the mode of distribution of new deoxyribonucleic acid among daughter chromosomes. It is both a difficult and important problem with far-reaching consequences. If a deoxyribonucleic acid unit is defined as a molecule or group of molecules that are synthesized and tied together, the possible hypotheses are as follows:

(*a*) The number of deoxyribonucleic acid units per chromosome is small and there is a mechanism that ensures a perfectly equal distribution of newly synthesized labelled units and old units among daughter chromosomes. This implies a definite spatial relationship between these units (or, less likely, a system that can distinguish between new and old units of identical composition).

(*b*) The number of units is small and they are randomly distributed among daughter chromosomes. On the average, two sister chromosomes have an equal amount of new and old deoxyribonucleic acid, but some pairs may show a very unequal distribution.

(*c*) The number of units per chromosome is large and there is a random distribution.

(*d*) The number of units is large but there is a tendency for the newly synthesized units to move together.

The experiments of Taylor *et al.* tend to prove hypothesis (*a*). Plaut and Mazia's results[3], taken at their face value, point to (*b*) or (*d*). Mine agree best with (*a*) and (*c*). It should also be borne in mind that there may be no single pattern of universal application.

Contrary to what Plaut and Mazia[3] say, all these hypotheses are compatible with the Watson and Crick hypothesis of duplication of deoxyribonucleic acid molecules : a simple calculation shows there are usually several thousands of these per chromosome, so that a different order of magnitude is involved.

Crucial experiments are difficult to devise in this field where matters are complicated by errors due to the random decay of the isotopes and to the methods of quantitative assessment of radioactivity. It seems, however, that if hypothesis (*b*) is correct, we should find some unlabelled anaphase chromosomes (in a species where their number is large) after one premitotic synthesis in the presence of a radioactive precursor. If in such an experiment *all* chromosomes are labelled, hypothesis (*b*) becomes extremely unlikely. With the precise localization given by tritiated thymidine (but not with thymidine labelled with carbon-14), such an experiment now seems possible and I intend to try to tackle the matter shortly.

Comparison of the Salivary Secretion of Both Parotid Glands in a Sheep

NUMEROUS workers have shown that the parotid glands of ruminants secrete saliva continuously, but only a small number of observations have been made on the secretion of both glands in the one animal. Scheunert and his colleagues[1] observed that the two parotids of sheep secrete independently of one another and considered it probable that the fistulated parotid secretes only a minimal amount of saliva. Colin[2] ascribed the differences in the secretion of the two parotid glands which he observed in the case of an ox to the preference on the part of the animal for chewing on the non-operated side.

In the course of investigations on the return of nitrogen to the rumen in the parotid saliva of sheep, the secretion from both parotid glands in a Merino wether was measured over fourteen days. Into each duct two cannulæ were inserted, one directed towards the gland, the other towards the orifice on the buccal mucosa. The free ends of the cannula on either side could be joined so that the saliva was able to flow into the mouth from one gland, while that from the opposite member was being collected. By reversing the opening and closing of the bridge from side to side, the daily secretion from each parotid gland was measured on alternate days. In this way the animal received the secretion from one gland at all times.

The collections were commenced three days after the surgical operation and continued for the following fourteen days. During this time the animal consumed the whole of its daily ration of 680 gm. of dry matter composed of sheep cubes, oat grain, oat chaff and lucerne hay. The animal had free access to water. Instead of giving the sheep a daily ruminal infusion of sodium bicarbonate to replace the sodium lost in the secretion from the operating gland, the remainder of the saliva collected, after samples had been kept for nitrogen analysis, was infused back into the rumen per cannulum at a rate simulating the natural flow.

For the duration of the experiment the animal was kept under the same environmental conditions to which it had been accustomed for the previous six months and maintained the same position in relation to its regular neighbours in the colony. It was attended by only one member of the department.

Under these conditions the daily volume was recorded for each gland on alternate days and the nitrogen content of the saliva determined by the micro-Kjeldahl method. The results are given in Table 1.

Table 1

Saliva	Left gland	Right gland
Total volume for 7 days (ml.)	16,665	17,468
Mean daily volume (ml.)	2,381 ± 94·3*	2,495 ± 94·3*
Range in daily volume (ml.)	1,992–2,745	2,268–2,775
Total nitrogen content for 7 days (mgm.)	2,076	2,007
Mean daily nitrogen (mgm.)	297 ± 10·6*	287 ± 10·6*
Range in daily nitrogen (mgm.)	257–327	251–341

* Standard error of mean

The mean daily volume of the left and right gland did not differ significantly (*t*, 0·86 on 12 degrees of freedom). Similarly in the case of the mean daily output of nitrogen, the left and right gland did not differ significantly (*t*, 0·66 on 12 degrees of freedom).

The mean daily volume of saliva and nitrogen content accord well with similar values recorded for sheep with permanent unilateral parotid fistulæ kept under the same feeding and environmental conditions at this Institute. Denton[3] has reported that the daily volume of saliva secreted by sheep with permanent unilateral parotid fistulæ is relatively constant on any one diet. However, the volume collected daily varies with the diet[4].

Both parotid glands continued to function for a further nine days until on the twenty-sixth day after the operation one of the cannulæ became dislodged. During the whole period of observation the animal did not appear to suffer any overt ill effect from the presence of the cannulæ in the ducts. It remained in good health, ruminated normally, and passed fæces of uniform consistency. Over the twenty-six days of observation the sheep gained 2·5 lb. in weight.

The procedure adopted of infusing the animal's own saliva back into the rumen as a continuous flow was designed to approximate the secretion of the saliva under normal physiological conditions and thus maintain the buffered fluid environment in the rumen. As an alternative I have observed that sheep with permanent unilateral parotid fistulæ will drink their own saliva, or that from another animal, and remain in a healthy condition without a daily supplement of sodium bicarbonate.

The significance of the salivary nitrogen contribution to the rumen under different dietary conditions will be discussed elsewhere.

Desertomycin, a New Crystalline Antibiotic with Antibacterial and Cytostatic Action

A REPORT was recently published[1] of a new antifungal antibiotic, flavofungin, from a previously unreported *Streptomyces* strain, *Streptomyces flavofungini*. This species produces, besides flavofungin, another antibiotic. Its presence was demonstrated by the paper-chromatographic examination of the fermentation fluid and of the crude flavofungin. The *Streptomyces* strain originally isolated produces much more of this antibiotic than of flavofungin, in contrast to its natural variant, which synthesizes flavofungin more abundantly. The second antibiotic can be extracted from the fermentation broth as well as from the mycelium with organic solvents. We succeeded in obtaining hexagonal crystals from various solvent systems (Fig. 1). This new antibiotic was named 'desertomycin', after the source (African desert sand) of the *Streptomyces* strain which produces it.

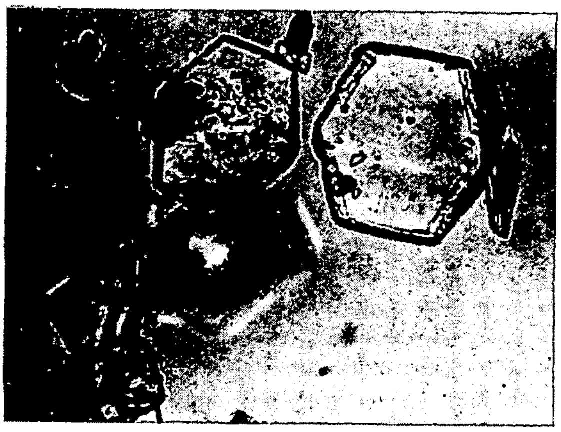

Fig. 1 Desertomycin crystals

Desertomycin is a uniform snow-white, glittering, crystalline product. Its tentative empirical formula is : $C_{33}H_{60-62}O_{14}N$. It melts at 189–190° C. The solubility in water or in absolute alcohols, ether and acetone is low, but it is higher in alcohols which contain some water. Its neutral aqueous solution is very stable. Desertomycin contains no sulphur, halogen, N-methyl or acetyl groups, but it has a C methyl group. The substance gives acetylated and hydrogenated derivatives ; it decolorizes a solution of permanganate or bromine and gives positive ninhydrin and Kuhn–Roth C-methyl tests.

Crystalline desertomycin was tested against a number of bacteria by a serial dilution method. The minimum inhibitory concentration varies between 5 and 25 μgm./ml. for various micro-organisms. The antimicrobial activity of desertomycin is shown in Table 1.

Table 1

Micro-organism	Inhibitory concentration (μgm./ml.)
B. subtilis, NTCC 6633	1–5
B. subtilis (streptomycin resistant)	1–5
B. subtilis (penicillinase producing)	1–5
B. megatherium	1–5
Staphylococcus aureus Duncan	10
Staphylococcus aureus (penicillin resistant) (three strains)	10
B. cereus 569	10
E. coli 111	10–25
E. coli S. (mouse-pathogen)	10–25
Staphylococcus aureus (mouse-pathogen) (two strains)	25
Staphylococcus aureus (four strains)	25
Staphylococcus aureus (poly-resistant)	25
Staphylococcus aureus (penicillin resistant) (five strains)	25
Micrococcus ureae	25
Enterococcus	>25
E. typhosa H	>25
E. coli commune	>25
Pneumobacillus Friedländer	>25
Pseudomonas pyocyanea	not inhibited

Desertomycin proved to be markedly toxic for mice. The intravenous, intraperitoneal, subcutaneous and oral *LD*50 of desertomycin in mice was found to be 1·35 mgm./kgm., 2·6 mgm./kgm., 5·3 mgm./kgm. and 12–15 mgm./kgm. body-weight, respectively.

Desertomycin exhibits a very significant cytotoxic effect. Our *in vitro* experiments show that it inhibits the life-activity of leukæmic cells and of Ehrlich ascites cells in a quantity of 0·7 μgm. and 10 μgm., respectively[2]. It exhibits a cytostatic (10 μgm.) and in higher concentrations (50–100 μgm.) a cytolytic action on fibroblast, HeLa and Crocker cells, studied by the tissue culture method (Kelner, B., *et al.*, personal communication). Once more the inhibition of the growth of bacteria is seen to be connected with the inhibition of tumour cells.

Adrenalectomy and Tissue Amines

WE have recently suggested[1] that the secretion of the adrenal cortex exerts a functional control over the levels in tissue of both histamine and 5-hydroxytryptamine. This evidence was obtained by injecting synthetic corticosteroid substances into normal rats as well as into rats in which tissue histamine had been previously depleted. Further experiments have now been carried out on animals the adrenal glands of which have been removed before drug treatment.

Groups of rats (100–125 gm. in weight) were bilaterally adrenalectomized and maintained for four days on a cube diet and either drinking water or normal saline solution. Other groups were mock-adrenalectomized and similarly maintained. The animals were then killed and several tissues extracted and tested for histamine and 5-hydroxytryptamine activity. Striking differences between the amine-levels in the groups were noted. Whereas the histamine-levels in the skin, ears, feet, liver and lung of adrenalectomized rats maintained on normal saline solution did not differ significantly from those of mock-adrenalectomized animals, the histamine-levels in these tissues of adrenalectomized rats maintained on water were increased two to six times. When cortisone (but not deoxycorticosterone acetate) was given to such animals, the histamine-levels in the tissues fell dramatically to normal levels or below. This is therefore a further demonstration of the control exerted by glucocorticoid substances on tissue histamine-levels, and as suggested by Schayer and his co-workers[2] these substances probably alter the rate of formation of histamine in the tissues. In a similar manner, there is a two-fold increase in the 5-hydroxytryptamine-levels in the tissues of adrenalectomized rats maintained on drinking water, and cortisone treatment restores these levels to normal. The changes in the 5-hydroxytryptamine-levels might be magnified if the experiment can be performed on histamine-depleted adrenalectomized rats maintained on drinking water, but such rats have not so far been available.

These results support our hypothesis[1]. They further show that the tissue-levels of both histamine and 5-hydroxytryptamine are in part inversely related to the sodium intake. The importance of the dietary sodium content when studying the effect of adrenalectomy on tissue histamine-levels was shown by Rose and Browne[3]; but neglect of this factor by later workers led to several conflicting results. In assessing the effect of corticosteroids on conditions of inflammation, conflict has also arisen due to lack of appreciation of the role of tissue amines in certain of these conditions and of the control exerted upon these amines by the hormones of the adrenal gland and their analogues. It is of interest that in the present experiments the fluctuations in the 5-hydroxytryptamine-levels in the rat follow those in the histamine-levels, and in this respect are similar to those noted already in other forms of stress such as weaning, pregnancy and hyperthyroidism[4].

Lethal and Sterilizing Effects of Single and Fractionated Doses of Gamma Radiation on *Calandra granaria* L.

Two techniques for radiation disinfestation can be distinguished: the direct irradiation of infested products[1], and the indirect control of a pest species by the release of sterilized adults[2]. The successful operation of the first method necessitates complete and permanent reproductive sterilization accompanied by premature death; and the second, sterilization without seriously affecting the longevity of the released adults.

The susceptibility of a number of insect species to large single doses of gamma radiation has been examined[3]. Small daily doses of X-rays[4] and γ-rays[5] have been shown to increase the longevity of the flour beetle (*Tribolium confusum* Duv.). Again, the sterilizing dose for the parasitic wasp (*Habrobracon juglandis* (Ashmead)) does not cause permanent infertility when fractionated with suitable time intervals between treatments[6]. As part of a broader project to examine the radiation susceptibility of grain weevils, preliminary experiments were carried out to compare the effects of single and fractionated doses of γ-radiation on larvæ and adult *C. granaria*. Insects were irradiated with a cobalt-60 source providing a dose-rate of 6 × 10^3 r./hr. Cultures were maintained on preconditioned grain at 26° C. and 75 per cent relative humidity.

Table 1. The Effects of Irradiating Larvæ of *C. granaria* with a Single Dose of 4,012 rep and Five Repeated Doses of 802 rep on Adult Emergence, Survival and Progeny Production

Treatment	Batches, each of 450 larvæ	Mean No. of adults emerged	Adult survival four weeks after emergence (per cent)	No. of progeny
Control *A*	2	105·0±5·5	99·1± 0·9	2,187± 59
Control *B*	6	115·0±3·3	98·9± 0·4	2,208± 40
Intervals between repeated doses:				
1 day	2	103·0±5·0	97·0± 2·1	1,621±213
1 hr.	1	47	66·0	51
10 min.	1	5	20·0	0
1 min.	1	2	50·0	0
Single dose	4	2·5±1·0	23·3±14·5	0

In the first experiment, batches of larvæ in grain were treated with a single dose of 4,012 rep and others with five repeated doses of 802 rep; the time intervals between treatments were 1 and 10 min., 1 hr. and 1 day. The single dose was applied to samples containing equal proportions of 7–8, 8–9, 9–10, 10–11 and 11–12 day-old larvæ. Similar samples were used when the intervals between repeated doses were 1 hr. or less. With daily doses, the first treatment was given to 7–8 day-old larvæ and the last on the eleventh to twelfth day of their development. Two types of untreated controls were used: *A*, larvæ 7–8 days old when the first daily dose was given and *B*, equal proportions of larvæ covering the age-range. The adults which emerged after treatment were placed to oviposit on 100 gm. of grain for four weeks. Table 1 shows the effects of irradiation on the emergence of adults, their survival and production of progeny.

In a similar experiment, batches of 50 adults 7–12 days old were treated with a single dose of 5,666 rep and others with five repeated doses of 1,133 rep; the 1-hr. interval between treatments was omitted. Controls *A* and *B* were used as in the first experiment. After irradiation the adults were placed to oviposit on 100 gm. of grain and the number of survivors counted four weeks later. Progeny were recorded 7 and 9 weeks after inoculation (Table 2).

Table 1 shows that when young larvæ are treated with a single dose and with doses fractionated by intervals of 1 and 10 min., adult emergence is markedly reduced; more adults emerge when the interval is increased to 1 hr., while with daily doses emergence is unaffected. These results suggest the existence of a recovery process which becomes completely effective a few hours after treatment.

Table 2. The Effects of Irradiating Adult *C. granaria* with a Single Dose of 5,666 rep and Five Repeated Doses of 1,133 rep on Survival and Progeny Production

Treatment	Batches, each of 50 adults	Mean survival after four weeks (per cent)	Mean No. of progeny (weeks after inoculation)	
			7 weeks	Total at 9 weeks
Control *A*	8	97·5±0·8	1,083±88·0	1,720±112·0
Control *B*	14	97·0±1·0	1,106±51·0	1,766± 48·0
Intervals between repeated doses:				
1 day	4	97·5±1·9	14± 0·6	53± 5·4
10 min.	3	10·7±0·7	10± 0·4	12± 0·6
1 min.	3	11·3±2·4	12± 3·0	14± 4·3
Single dose	7	5·1±1·1	11± 0·6	12± 0·8

In the Defence White Paper published this year, it was announced that Great Britain was engaged in the design and development of 'a most advanced type' of ballistic missile. de Havilland Propellers Limited is the overall design authority for that work and invite applications for the following senior appointments:

- **ENGINEERING PHYSICIST**
- **MOTOR CONTROL SYSTEMS ENGINEER**
- **PNEUMATIC SYSTEMS ENGINEER**
- **FUEL SYSTEMS ENGINEER**
- **SENIOR DEVELOPMENT ENGINEER**

advanced design in **HIGH VACUUM EQUIPMENT**

GeneVac LTD

GENEVAC ROTARY PISTON PUMPS

- ★ Available in displacement capacities of 2, 4, 8, 12 cu.ft./min.
- ★ Full gas ballast control supplied standard on all pumps.
- ★ Ultimate vacuum less than 0.005 mm. Hg single stage.
- ★ Ultimate vacuum less than 0.0002 mm. Hg two stage.
- ★ Higher pumping speeds at 100 microns.
- ★ Oil circulation continuously filtered.
- ★ Pressure rise less than 0.5 mm. Hg with max. ballast.
- ★ Oil change operation reduced to a minimum.

★ FOR FURTHER INFORMATION WRITE TO:

GENEVAC LTD.,
PIONEER MILLS, RADCLIFFE, LANCS.
Telephone: RADCLIFFE 3041–2.

IRGA

GENERAL PURPOSE DIRECT DEFLECTION INFRA-RED GAS ANALYSER

- ★ Single infra-red source, completely enclosed
- ★ Three ranges (1 : 10 : 100) with instantaneous range changing (patented system) available as an extra.
- ★ Electronically operated synchronous rectification resulting in low sensitivity to vibration
- ★ A.C. Stabiliser incorporated to give immunity to mains fluctuations
- ★ Stout case with provision for purging to meet flameproofing requirements

Table 1 also shows that the survival of adults and production of progeny are similarly affected.

Table 2 shows that the survival of adults which are treated with fractionated doses is also similar to that obtained with a single dose if the interval between treatments does not exceed 10 min.; furthermore, after treatment with daily doses their survival is similar to the controls. Production of progeny, however, is seriously reduced by both single and fractionated doses, irrespective of their duration, and in this respect adults and larvæ differ markedly in susceptibility. However, the difference in progeny counts at 7 weeks and at 9 weeks suggest that fertility may reappear in adults receiving daily doses. The difference in behaviour of larvæ and adults may be attributed to the condition of gonadial development at the time of irradiation and warrants further investigation.

The present results are of importance in relation to the operation of the two techniques for radiation disinfestation. Thus, the efficacy of direct irradiation of infested products could be seriously jeopardized by the use of repeated passes if intervals between doses are longer than a few minutes. On the other hand, an increase in longevity, obtained by using fractionated doses at daily intervals, could considerably increase the efficiency of insect control by the release of sterile adults provided permanent sterilization was achieved.

Dosage-Mortality Curves for Houseflies Susceptible and Resistant to DDT

A recent paper by Hewlett[1] has directed attention to the fact that the slopes of dosage-mortality curves for houseflies resistant to DDT are less steep than those for houseflies susceptible to DDT; he explained this in terms of (1) the relation between the amount of DDT absorbed by flies and the external dose; and (2) a possible variation from fly to fly of the DDT exerting a toxic effect at the primary site of action, a variation brought about or intensified by enzymatic detoxification of DDT in resistant flies. An alternative explanation of the phenomenon would be that DDT resistance in houseflies is genetically controlled, and that very few of the strains of insects so far examined represent genetically pure lines.

Let us take the case of an insect the resistance of which is governed by a single incompletely dominant gene *R*. Possible genotypes are then *RR*, *Rr* and *rr*. Even if the fully susceptible *rr* genotype is eliminated in each generation, the progeny of the heterozygote cross *Rr* × *Rr* will consist of 25 per cent of fully susceptible individuals. Unless, therefore, a pure line of *RR* constitution can be isolated from its allelomorphs, a dosage-mortality test of flies of a given generation will show a response of individuals ranging from complete susceptibility to the highest resistance expressible by the gene in question. Since in Nature the occurrence of resistance genes is normally so low that in an average sample of wild insects none will be found, the control will therefore represent a purer line of susceptibility than the resistant does of resistance. The difference in the slopes of the two dosage-mortality curves is therefore representative principally of the difference between the pure and the impure samples.

In the case of polygenic resistance, due to a number of weak genes acting together—to which type of resistance most cases of housefly resistance apparently belong—the picture is similar, but less simple. Let us take the case of two independently segregating partially dominant resistance genes *R* and *P*. There are then nine different possible genotypes, ranging from the highest resistance *RRPP* to the lowest (fully susceptible) *rrpp*, all of which may appear in any new generation. Given three genes, 27 possible combinations may occur. Separation of the genotypes is then virtually impossible, for any mass selection technique of exposure of a given generation to insecticide may still leave some heterozygotes alive, which will give rise to susceptibles and further heterozygotes at the next generation.

In the case of a pure line the difference between the *LD*0 and the *LD*100, that is, the slope of the curve, will be dependent entirely upon the inherent errors in the methods of sampling and testing, plus a certain fly-to-fly variation. In the case of a mixed strain, this difference will obviously be greater by the extent to which the component genotypes differ one from another. However, the establishment of a greater number of points on the dosage-mortality curve, that is, by testing a greater number of dosages intermediate between *LD*0 and *LD*100, may lead to the resolution of the gently sloping resistance curve into several parallel curves equal to the number of the genotypes present.

Fig. 1 shows the three separate log-probit regression lines for the three genotypes of the Western Sokoto strain of *A. gambiae* exposed to various concentrations of gamma-BHC. Resistance to dieldrin and BHC has been shown to be monofactorially inherited and incompletely dominant in this strain[2]. Super-imposed on these three regression lines is the graph for an F_2

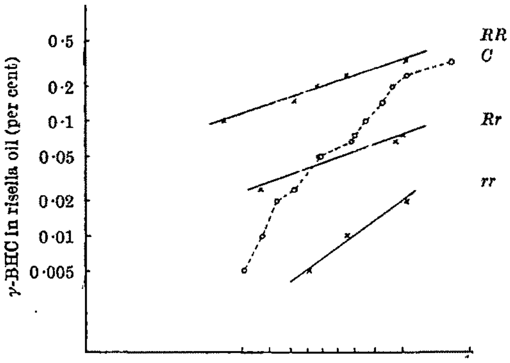

Fig. 1. Log-probit regression lines for susceptible (*rr*) hybrid (*Rr*) and resistant (*RR*) strains of *A. gambiae* exposed for 1 hr. to varying concentrations of gamma-BHC in risella oil and calculated percentage mortalities in a theoretical F_2 generation composed of 25 per cent susceptibles, 50 per cent hybrids and 25 per cent resistants (*C*) •

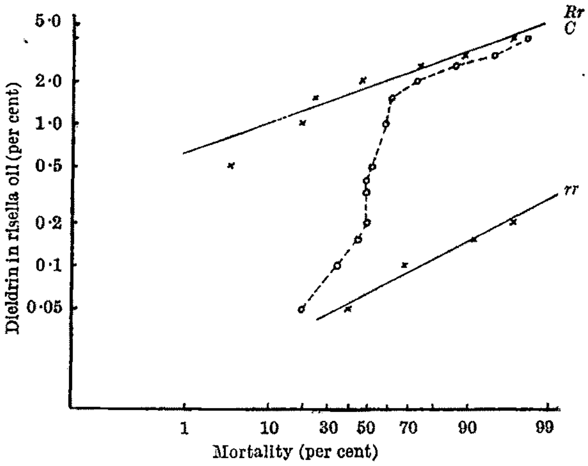

Fig. 2. Log-probit regression lines for susceptible (*rr*) and hybrid (*Rr*) strains of *A. gambiae* exposed for 1 hr. to varying concentrations of dieldrin in risella oil and calculated percentage mortalities in the theoretical backcross offspring (50 per cent susceptibles and 50 per cent hybrids) of a hybrid to the susceptible parent (*C*)

generation, composed of the theoretical 25 per cent susceptibles, 50 per cent hybrids and 25 per cent resistants, based on the actual mortalities recorded for the separate strains. A tripartite segregation of this graph is indicated though not too obviously and the points could be taken as lying on a single straight line. The explanation for this is that the degree of resistance to gamma-BHC is of a comparatively low order (some thirty times) and the gaps between the *LD*100 of the susceptibles and *LD*0 of the hybrids and *LD*100 of the hybrids and the *LD*0 of the resistants are very small. Resistance to dieldrin is much higher (some 800 times) and Fig. 2 shows the regression line for the theoretical offspring of the backcross of hybrids with the susceptible parent (50 per cent susceptibles and 50 per cent hybrids) based on mortalities recorded among susceptible and hybrid strains. A definite step in the line separating the susceptible part of the population and the hybrid part is apparent, where an increase in dosage produces no increase in kill (0·1–0·4 per cent dieldrin). As the degree of resistance to dieldrin is so high it is not possible to show the regression line for the resistant strain on this graph, where mortalities have been recorded after one hour's exposure to various concentrations of the insecticide. At this exposure time no kill at all is recorded with the resistant strain even on a saturated solution of dieldrin in risella oil. It will be seen from these graphs that on taking a sample of a resistant population produced by mass selection, the difference between the *LD*0 and the *LD*100 would be very much greater than in the case of any of the component lines.

The paper of mine referred to pointed out that it was not yet possible to say whether the two effects discussed would account for the whole of the differences between the slopes of probit–log-dose lines for houseflies resistant and susceptible to DDT. Additional genetic heterogeneity in strains of resistant flies could, it seems, operate side by side with the other two effects in reducing the slopes of the lines; it might also intensify the second of the other two effects. When applied to resistant flies with DDT, *bis*(*p*-chlorophenyl) methyl carbinol synergizes the action of the DDT by depressing its enzymatic detoxification[1,2], and at the same time increases the slope of the line relating probit mortality to the log-dose of DDT[2]; this strongly suggests that the detoxification mechanism is directly concerned in depressing the slope of the line for DDT without synergist, as discussed in my paper.

Ecology of the Louse *Lepidophthirus macrorhini* Enderlein 1904 on the Elephant Seal *Mirounga leonina* (L.)

The Australian National Antarctic Research Expeditions have maintained a station since 1948 on Macquarie Island, which is situated in the South Pacific, 54° 30′ S., 159° E. Through the courtesy of the director, Mr. P. G. Law, a visit was paid to the island in December 1957. This afforded an opportunity to obtain some information on the ecology of the louse *Lepidophthirus macrorhini* Enderlein 1904 which infests the elephant seal, *Mirounga leonina* (L.). Living lice were brought back to the laboratory for study by keeping infested hind flippers in a refrigerator.

Unlike other species of lice, *L. macrorhini* forces its way into the skin and creates a burrow under the stratum corneum of the epidermis. Single nymphs or adults were found in these burrows, usually with the posterior tip of the abdomen visible. Occasionally the burrows were half an inch in length. In addition, a copulating male and female were found in one burrow, and in two others, each inhabited by a single female, an egg was found. When the elephant seal moults the stratum corneum of the epidermis is shed intact with hairs attached. Although some lice are lost at this time many remain, since only the roof of the burrow which they inhabit is removed.

Pup seals were found to be the most heavily infested and the region of densest infestation was the hind flippers. From examinations made while the pups slept on the beach, it appeared that all were infested with lice.

The skin temperature of elephant seal pups and bulls (2–7 years old) resting on the beach was found to be between 27° C. and 34° C. Two pups were driven into the sea, after their skin temperatures had been taken, and restrained in 3 ft. of water by a lassoo around the neck. On entering the water their skin temperatures dropped to between 10° C. and 12·5° C., that is, a few degrees above the temperature of the sea, 8·5° C. These observations agree with those of Irving and Hart[1] on the harbour seal *Phoca vitulina* and the harp seal *Phoca groenlandica*.

In the laboratory it was found that the lice became inactive either in air or water at 10° C. When placed in moist air at 29° C., after an exposure to low temperatures for several days, normal activity did not return until after a few hours. Their oxygen consumption in air at 10° C., measured by a Warburg apparatus, dropped to at least a fifteenth of that at 33° C., and they survived a five-day immersion in sea-water at 10° C. which was only about 7 per cent saturated with oxygen (0·53 ml. oxygen per litre). Thus, at low temperature their metabolic rate was considerably reduced. It therefore appears likely that the skin temperature of the host is the primary factor which influences the growth of a population of these lice and that the main increase occurs when the skin temperature is highest, namely, when the elephant seal is on land. As a consequence, the age group which spends the longest continuous period ashore might be expected to become the most heavily infested. Pups comprised this group at Macquarie Island in December 1957.

It has been suggested that when the seal is at sea the lice obtain oxygen from a film of air trapped around the seal's body[2]. Examination of pups restrained in the sea showed that no film of air was trapped around the body, nor was one seen when the hind-flippers of pups, anæsthetized with chloral hydrate, were immersed in sea-water. Numerous small bubbles were held at the base of the hairs, in the orifice of the follicle, but were easily removed by gently running the fingers over the body. However, air bubbles which were sometimes retained in the burrows were not so easily removed.

Another suggestion has been that oxygen is obtained from air bubbles or from a film of air trapped between the characteristic setæ and scales found on this type of louse[3]. When lice were immersed in sea-water, a small bubble of air was occasionally attached to a seta but not necessarily to one of those surrounding the spiracles. More frequently, no bubbles were present and, as the cuticle of the louse was easily wetted, a film of air was not held around the insect. When completely wetted and immersed in fresh sea-water at about 10° C. the lice remained alive for more than two weeks.

As the cuticle is thin and transparent a microscopical examination of living lice in sea-water was made with transmitted light. Only abdominal spiracles were seen, with trachea leading from the anterior of the abdominal tracheal trunks to each of the limbs and the head. It was found that when a spiracular opening was surrounded by an air bubble regular contractions of the atrium commenced. When the bubble was removed these contractions ceased within a few hours. During this period no water was seen to enter the atrium, which was filled with a bubble of gas, some of which was occasionally expelled. As no other structure was seen which could have a respiratory function, it would appear that oxygen is obtained from sea-water by diffusion through the cuticle.

There appears to be no reason to doubt that sufficient oxygen can be absorbed through the cuticle. At the greatly reduced metabolic rate associated with the lowered temperature in sea-water, little oxygen would be required and the surface waters in the sub-Antarctic are usually more than 80 per cent saturated with it[4]. Moreover, the surface area of the cuticle of these lice is greatly increased by deep clefts in the intersegmental regions of the thorax and abdomen.

One function of the setæ, which in the living insect stand erect from the cuticle, is probably to maintain a space between the cuticle of the louse and the walls of the burrow in the seal's skin. This would enable a film of water to be maintained around the insect through which gaseous diffusion can take place. Also, any air bubble trapped in the burrow around the louse would be maintained and act as a gill.

It is hoped to continue these investigations and the co-operation of any biologist who intends to visit the sub-Antarctic would be most welcome.

Natural Relationships of the Nitrogen-fixing Bacteria

In a recent publication, Hino and Wilson[1] describe the fixation of nitrogen by a bacterium strongly resembling *Bacillus polymyxa*. The significance of this finding should not escape notice, as it has an important bearing upon a long-standing controversy.

The existence of a Gram-positive, sporogenous form of *Azotobacter* was demonstrated by Löhnis and Smith[2] but their claims were disregarded. Much later, I showed[3] that many strains of *Rhizobium* pass through a Gram-positive, sporogenous phase, and expressed the opinion that this genus is related to *Bacillus polymyxa*. Afterwards, the work of Löhnis was confirmed and extended[4], and it was concluded that *Azotobacter* and *Rhizobium* are both specialized members of the Bacillaceae; with the important corollary that they were thus shown to be closely related to *Clostridium*, many species of which are capable of fixing nitrogen[5].

The members of the *Bacillus polymyxa* group differ from other aerobic sporing bacilli in possessing a clostridial spore and in producing gas from carbohydrates, but they share these characters with *Clostridium* and with the sporogenous strains of *Rhizobium* and *Azotobacter*. It now appears that they also share the ability to fix nitrogen.

Since it is very often stated that morphology is of limited value in the classification of bacteria, it is worth placing on record that the evidence which led me to the conclusion that *Bacillus polymyxa* is closely related to the nitrogen-fixing bacteria was almost entirely morphological.

Growth-promoting Activity of Potato Tuber Extracts in the Coleoptile Straight-Growth Test: Quantitative Aspects of Indoleacetic Acid Detection

THE development of relatively simple techniques for the chromatographic separation of growth-active fractions from plant extracts, and their detection by chromogenic reagents, has led to the conclusion that indoleacetic acid and other indole compounds are the principal naturally occurring growth substances, as detectable in the coleoptile straight-growth test. In many instances, however, the characterization of growth-active fractions as indole or non-indole compounds has been based on insufficient evidence, or lack of awareness as to the sensitivity or specificity of the techniques used. For example, the growth activity in extracts of potato tubers has been ascribed to the presence of several indole compounds[1-3], yet no single investigator has demonstrated a correlation between colour reaction and biological activity for chromatograms developed in a number of solvent systems.

During the course of an investigation into the growth-substances present in developing and stored potato tubers, it was found that in the ether fractions from approximately fifty separate ethanol extracts there was present only one promoter of coleoptile growth. This ran at the position of indoleacetic acid in *iso*propanol : ammonia : water, butanol : ammonia: water, butanol : acetic acid : water, and ethanol : formic acid : chloroform : water solvents. Nevertheless, even when a 500 gm. fresh weight equivalent was chromatographed on a 10 cm. wide paper and strips from this sprayed with Ehrlich's reagent a colour reaction was not given. The failure of the growth-substance to give an indoleacetic acid colour reaction with chemical reagents, even though it appeared to be identical with the indoleacetic acid from chromatographic evidence, was investigated further as it seemed possible that the amount present might be below the minimum quantity detectable with such reagents. Known quantities of indoleacetic acid were distributed over 3 cm.^{2} areas of filter paper and sprayed with reagent; from 0·2 to 0·5 μgm. indoleacetic acid gave a faint, transient colour with Ehrlich's reagent and 5 μgm. was required to give a strong, more permanent colour. Salkowski's reagent was slightly less sensitive. From the results of bio-assay and assuming that the promoter was indoleacetic acid, it was determined that a little less than 1 μgm. would be present in the 500 gm. equivalent tuber fraction and, as 10 cm. wide paper was used, this was distributed over an area of 30 cm.^{2}. This concentration, although giving considerable growth stimulation on bio-assay, would therefore be well below the limit of detection with chemical reagents. In order to be certain of getting a colour reaction, if the promoter was indoleacetic acid, it was calculated that the extract from 3 kgm. of tubers would have to be localized in an area of 3 cm.^{2} of paper. This was achieved by repeated chromatography and elution, and with Ehrlich's reagent a colour reaction typical of indoleacetic acid was given. Recently it has been shown that some sugars[4] and other compounds[5], probably leucoanthocyanidins, give colour reactions which may be confused with those given by indoleacetic acid. These substances were not responsible for the colour reaction of the potato extracts.

It is clear from the results relating to the sensitivity of the chemical reagents used for the detection of indole compounds that care must be taken to use a sufficient quantity of material in order to detect a chromogenic reaction. The failure of certain other workers to obtain colour reactions at growth-promoting zones running at the same position as indoleacetic acid on chromatograms might well be due to lack of material.

In the present investigation it appeared that the only ether-soluble growth promoter of potato tubers was indoleacetic acid. The discrepancies between the present results and those of earlier workers, who reported two or three further indole compounds, may be a consequence of differences in extraction technique. In this work material was frozen solid, powdered and allowed to thaw in ethanol. Under these conditions the tissue remained perfectly white throughout extraction. *p*H adjustment was not made during extraction or in the separation of an initial ether fraction; but a further ether extract, made at *p*H 3, yielded no other promoters.

δ-Acetylornithine : a Constituent of some Common Grasses

Two acetylornithines have been identified as natural products. α-Acetylornithine is accepted as an intermediate in the major pathway in the biosynthesis of ornithine from glutamic acid in *Escherichia coli* and has been isolated from culture filtrates of a mutant strain of this organism requiring ornithine[1]. δ-Acetylornithine was isolated somewhat earlier from the roots of *Corydalis ochotensis* by Manske[2]. It is also present in *Corydalis bulbosa*, and has been isolated as its dihydrochloride from the fern, *Asplenium nidus*[3]. In a private communication, Prof. K. Mothes tells me that he and Dr. G. Reuter have extended Manske's findings and have shown that δ-acetylornithine is present in large amounts in nearly all the members of the Fumariaceae (of which *Corydalis* is a member) that they have examined.

No information is as yet available to indicate the way in which δ-acetylornithine is implicated in intermediary plant metabolism. This may be due largely to the unsuitable nature for metabolic experiments of the plants from which it has been isolated. Therefore it seems appropriate to report that the amino-acid has now been identified as a constituent of a number of common grasses of the tribe Festuceae. In order to confirm its chemical character it was isolated from a representative member of these species, *Brachypodium sylvaticum*.

By means of cation-exchange resin ('ZeoKarb' 215) and paper partition chromatography, approximately 50 mgm. of δ-acetylornithine were isolated from an aqueous ethanolic extract of 500 gm. of macerated leaves of *Brachypodium*. The identity of the substance was confirmed by elementary analysis (found : C, 48·0 ; H, 8·2 ; N, 15·8 ; calculated for δ-acetylornithine, $C_7H_{14}O_3N_2$: C, 48·3 ; H, 8·0 ;

N, 16·1 per cent), and by comparison with authentic samples of δ-acetylornithine obtained from Profs. K. Mothes and A. I. Virtanen. The substance from *Brachypodium* was inseparable from δ-acetylornithine when run on paper chromatograms developed in four different solvent systems. In contrast, it could be separated from α-acetylornithine (kindly supplied by Dr. H. J. Vogel) on chromatograms developed in *n*-butanol/acetic acid mixture and in 70 per cent (v/v) *n*-propanol. The isolate had a melting point of 265° C.; no depression of the melting point resulted when the isolate was admixed with δ-acetylornithine (melting point, 265–266° C.). When hydrolysed with *N* hydrochloric acid at 100° C. for 24 hr., the isolate gave rise to ornithine which was identified chromatographically.

Although δ-acetylornithine is normally a major component of the free amino-acid pool of the members of the Fumariaceae, it was a relatively minor component of *Brachypodium* and, in the grasses examined, it never accumulated in concentrations comparable with those of certain of the common protein amino-acids. δ-Acetylornithine was not present in the leaves of two common cereals examined. Small amounts of another amino-acid, provisionally identified as α-aminoadipic acid, were found in the extracts of most of the grasses. The relative amounts of δ-acetylornithine and α-aminoadipic acid present in each species are listed in Table 1. Occasionally β-alanine or pipecolic acid also was found in an extract together with many of the normal protein amino-acids.

Table 1. RELATIVE AMOUNTS OF δ-ACETYLORNITHINE AND α-AMINOADIPIC ACID IN EXTRACTS PREPARED FROM LEAVES OF VARIOUS GRASSES

Species	δ-Acetylornithine	α-Amino-adipic acid	Other acids
Agropyron repens	*	*	β-Al: *W*
Brachypodium sylvaticum	*M*	*W*	*
Bromus carinatus	*	*W*	*
Dactylis glomerata	*	*W*	PA: *M*
Festuca heterophylla	*W*	*W*	*
Lolium perenne	*T*	*W*	β-Al: *W* PA: *M*
Poa glauca	*S*	*W*	*
P. nemoralis	*M*	*W*	*
P. alpina	*W*	*W*	*
P. pratensis	*M*	*W*	*
Puccinellia maritima	*M*	*	*
Barley (*Hordeum vulgare*)	*	*W*	*
Oats (*Avena sativa*)	*	*T*	*

Key: *S*, relatively large amount; *M*, moderate amount; *W*, small amount; *T*, trace amount; * not detected; β-Al, β-alanine; PA, pipecolic acid.

The ready availability of seeds of a number of the grasses investigated and the vigour with which they grow should make these species more suitable than the Fumariaceae for future study of the way in which δ-acetylornithine metabolism is related to the basic, well-established patterns of nitrogen metabolism in the higher plant.

My thanks are due to Miss J. Chessun for technical assistance.

Photoperiodic Response of the House Sparrow, *Passer domesticus*

FORTY-SIX male sparrows were divided into two groups and placed in light-tight cages 6 ft. × 6 ft. × 6 ft.

Group 1. Twenty-four birds were given a photoperiodic treatment of 7 hr. light and 17 hr. darkness per 24-hr. period. Light was from two 40-watt daylight fluorescent tubes which gave never less than 7 ft.-candles in any part of the cage. Group 2. Twenty-two birds were given a photoperiodic treatment of 1 hr. light and 23 hr. darkness per 24-hr. period. Light was from a single 15-watt incandescent bulb which gave 1 ft.-candle or less on perches and floor.

The experiments were started in February 1957 and two specimens were taken from each group every month. Testis volume was obtained from measurements of the axes of the organs immediately upon dissection and afterwards sections were cut at 5μ and stained to show the stages of spermatogenesis. In addition, as many wild controls as it was possible to obtain were collected in the immediate environment and were given the same histological treatment as experimentals.

The testis volume and stage of spermatogenesis of controls, group 1 and group 2 are shown in Figs. 1 and 2. It is concluded that:

(1) The minimal threshold-level in respect of photoperiod is down to at least 1 hr. in this species.

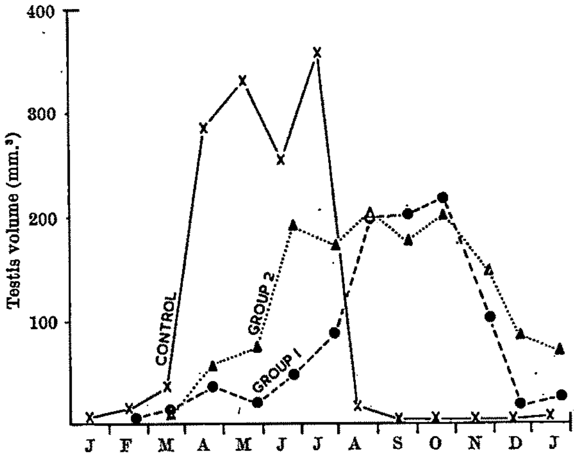

Fig. 1. Testis volume. Groups 1 and 2, average of two specimens each month. Control, average of all specimens each month

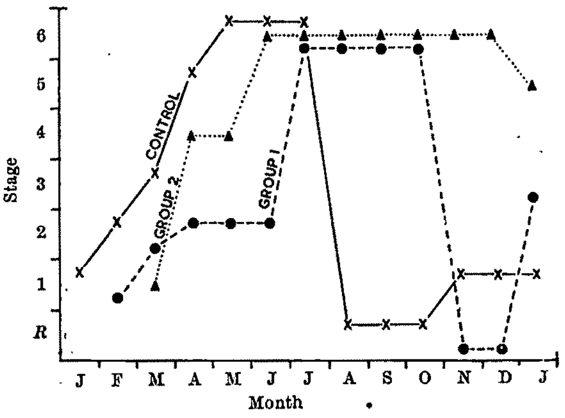

Fig. 2. Spermatogenesis. Groups 1 and 2, maximum stage of spermatogenesis of two specimens each month. Control, maximum of all specimens each month

This level is very much lower than has previously been recorded for any other bird. Bartholomew[1] considered 10 hr. to be close to the minimal level for the sparrow, but subjected birds to this photoperiod for only 46 days.

(2) The effectiveness of a photoperiod is dependent not only on its length but also on the duration of its application. In both group 1 and group 2 only slight testicular response was evident after 4 months and 3 months respectively. In estimating the minimal photoperiodic threshold for any bird, therefore, it appears necessary to conduct experiments for at least 6 months.

(3) The relationship between length of photoperiod and time of maximum testicular response, that is, production of spermatozoa, does not seem to be a straight-line correlation. Further research may show this relationship to be parabolic, with the minimal response centred at a 7- or 8-hr. photoperiod and the response increasing from this low in both directions.

(4) The duration of production of spermatozoa appears to bear a certain inverse relationship to the length of the photoperiod. On 1 hr., spermatozoa were produced for 214 days, with 7 hr. for 122 days and under natural conditions for 98 days. A relationship between photoperiod and duration of spermatogenesis has been noted by Burger[2] for the starling. In this bird the rate of testicular activation increased from 8·5 to 24 hr. but the duration of spermatogenesis was maximum at 12·5 hr. and decreased for both longer and shorter photoperiods. The results given here are in contrast with those of Burger because a 1-hr. photoperiod, when compared with a 7-hr., not only extended its duration but also induced a more rapid spermatogenetic activation.

The extension of the potential breeding season in this bird by artificial means is only the third recorded case known to me. Wolfson[3] reported the maintenance of active testes in Fringillid birds for almost a year on 12 hr. and on 20 hr. starting on April 6.

(5) The inherent tendency to testicular involution can be modified by photoperiodic treatment. The tendency seems to be 'put off' by short photoperiods (see 4). Furthermore, recovery from collapse is more rapid under a short photoperiod and this is shown in group 1, where only 1 month after complete regression, spermatogenesis had proceeded to stage 3, while the testes of controls were at stage 1. This conclusion is in agreement with the findings of Burger[2] for the starling and Wolfson[4] for the junco and white crowned sparrow.

(6) The testicular cycle of this bird is under the control of two separate mechanisms, one stimulatory and the other inhibitory but both under photic control. The separateness of these two mechanisms is indicated in that more rapid activation of the testes does not necessarily result in a rapid regression. Group 2 showed a more prompt response than group 1 and attained testicular volumes comparable with the latter but had not regressed as completely by the end of the experiment. It seems reasonable, therefore, to postulate separate mechanisms. The results here suggest that there is some direct relationship between the amount of inhibitory substance produced and the photoperiod; for example, very little is apparently produced by 1 hr., as regression was only partial, sufficient for regression by 7 hr., but as re-activation of the testis is rapid, its effect must be soon destroyed, and most under natural conditions when, after collapse in August, reactivation does not occur until November or December. There is, therefore, some suggestion that the effectiveness of the inhibitory substance is destroyed by long nights.

The results of these experiments are very similar to those I have already obtained in respect of the pigeon *Columba livia* (unpublished). Further experiments are, of course, necessary, and the following are at present in progress: 1 hr. light and 23 hr. darkness and 4 hr. light and 20 hr. darkness, both with an intensity of not less than 7 ft.-candles; 4 hr. light and 20 hr. darkness with an intensity of 1 ft.-candle or less on perches and floor. It is hoped to publish a full report of these results together with those of the new experiments when the latter are completed.

This work was carried out while I was the holder of a National Research Council of Canada Post-Doctorate Fellowship. I wish to express my appreciation to Dr. H. I. Battle, for providing laboratory and other research facilities in the Department of Zoology, University of Western Ontario.

The Hood of the Hooded Seal, *Cystophora cristata* Erxl.

It is well known that the male of the hooded seal, *Cystophora cristata*, can inflate its hood, which is the greatly enlarged skin of the snout. It is also known that the male hooded seal can extrude an assumed pair of fiery red bladders or balloons through his nose. The presence in the nose of two evertible cœca, which would apparently be turned inside out in much the same way as glove-fingers, was claimed by Mohr[1] from the study of a museum specimen.

Having spent a few seasons on Norwegian commercial sealers in East Greenland waters I am able to throw additional light on this particular feature. Although I looked particularly for the evertible cœca, no such structures could be found on freshly killed animals. On several occasions I had the opportunity to examine males which were known with certainty to have extruded a fiery red bladder just prior to capture.

Having questioned several skippers and gunners, and having at last seen the phenomenon myself, I am now certain that one bladder only is extruded. Some of the skippers, who have excellent opportunities to observe the animals from the mast-head, state that when the bladder is beginning to be extruded it looks as if two are present, but, when fully inflated, one only is seen. It appears that the bladder is divided distally into two lobes, the whole structure in the inflated state being heart-shaped when viewed from above.

In males having a well-developed hood, the mucous nasal septum which divides the nasal cavity into two equal halves is also very well developed and is rather thick and elastic, the cartilaginous nasal septum remaining short. The extrusion of the bladder may be explained as follows: by closing one nostril, and by blowing out air through the nose, the mucous nasal septum is made to bulge into the opposite half of the nasal cavity and is extruded through the opposite nostril as a red bladder. The extrusion of this bladder appears to be confined to the breeding and mating season in the spring.

Nothing in the work of Brönsted[2] is thought to be contrary to the view expressed here.

It would be of interest to know if the male elephant seal, *Mirounga leonina*, the proboscis of which is similar to that of the hooded seal, can extrude a bladder through the nose in the same way.

Genetic Hazard of Ionizing Radiations

In current estimates of the genetic hazard of ionizing radiations to man[1] [2] four important assumptions are made: (1) that the mutagenic effect of a given radiation dose to the gonads is independent of dose-rate; (2) that the relationship of mutation-rate to accumulated dose is linear; (3) that the spectrum of radiation-induced mutation is similar to the spectrum of spontaneous mutation, and (4) that a dose of about 30–80 rads induces as much mutation as occurs spontaneously per generation ('doubling dose'). Assumptions (1), (2) and (3) derive largely from experiments with *Drosophila*; assumption (4) derives in part from the fact that a spermatogonial doubling dose of this order was estimated for seven specific genes in the mouse from observations of the spontaneous mutation-rate[3,4] and from experiments[4] in which adult males were given a high X-ray dose at a high dose-rate (600 rads, 90 rads/min.), the validity of assumptions (1), (2) and (3) being presupposed.

However, Russell and Kelly[5] have recently stated that they have found a much lower induced spermatogonial mutation-rate at these loci when the dose of 600 rads was given as cæsium-137 γ-rays at a low dose-rate than when it was given as 250 kV. X-rays at a high dose-rate. This means that for mouse spermatogonia one can no longer make assumption (1) and that estimates of the doubling dose will vary with the conditions of irradiation. Since man is likely to resemble the mouse more than *Drosophila* in this respect one can no longer make assumption (1) for man. Most genetically effective radiation exposure of man is due to low doses accumulated over an appreciable fraction of the life-span; it therefore becomes important to have some estimate, however rough, of the mutagenic effect of radiation delivered to the mouse under conditions more nearly comparable with those of most human exposure.

During the past ten years we have been carrying out two such experiments. In the present experiment young adult male mice accumulate 37·5 rads as cobalt-60 γ-radiation over 35 16-hr. nights. They are placed with females immediately after exposure and are bred for up to two years, so the great majority of gametes tested were spermatogonia at the time of exposure. Progeny of exposed and control males are scanned for recessive mutation at the *a*, *b*, *c*, *d*, *se*, *p* and *s* loci and for dominant visible mutation at any locus. The stocks and techniques used have been described elsewhere[6]. The results are summarized in Table 1, together with those from our earlier experiment[6] in which radium γ-rays were used. They yield an estimate of 95 rads for the doubling dose for the seven specific loci, which is higher than previous estimates[1,3] by a factor of 2 or 3. However, the lower 95 per cent confidence limit[7] is only 10 rads and therefore the data do not warrant any change in assumption (4). More than anything else they show the enormous numbers of animals that must be raised in low-dose mutagenesis studies: clearly at least a million more mice must be scanned before we shall have an estimate of the spermatogonial doubling dose that approaches precision.

Table 1

Dose (rads)	Progeny scanned	Specific locus mutations *a*	*b*	*c*	*d*	*se*	*p*	*s*	Total	Dominant visibles
0	18,355*	0	0	0	1	0	0	1	2	0
0	99,372†	0	1	0	3	‡	1	1	6	2
37·5	10,024*	0	0	0	0	0	0	1	1	0
37·5	53,298†	0	2	0	3	0	0	0	5	1

* Data from ref. 6; radium γ-rays used.

† Includes data from ref. 3: cobalt-60 γ-rays used.

‡ Two of the *d*-mutants were also mutant at the closely linked locus *se*. These have been counted as single mutational events in the analysis.

These results have a bearing also on assumption (3). In our experiments *d* has been the most mutable locus, there having been as many mutations at this locus alone as at the other six loci together; but in his high-dose, high-dose-rate experiments Russell[4] found only six *d*-locus mutations among a total of 54, the most mutable locus being *s*, with 25 mutations. Thus in this small sample of loci the spectrum of mutation induced by a high acute dose, on one hand, differed from that of spontaneous mutation and mutation induced by a low chronic dose, on the other. Clearly the validity of assumption (3), as applied to larger samples of loci, requires further test.

Possible Autosomal Linkage in Man

Familial intestinal polyposis is known to be an inherited dominant disease[1]. Most families die out after a few generations as the condition frequently causes death before reproduction has occurred, and affected individuals often refrain from marriage because of the danger of passing the condition on to their offspring.

In New Zealand a pedigree is being studied which consists of nearly two hundred individuals covering six generations. This pedigree contains eight families segregating for polyposis. A preliminary investigation, designed to test for possible linkage relations, has suggested that the polyposis gene may be closely linked to the *MN* locus. The method used is that described by

Finney[2]. Of the eight families, one must be rejected as the parent with polyposis is group *M*, and in three families the parent affected with polyposis died before the investigation was begun and examination of the offspring is not sufficient to be able to determine the mating type with certainty. One further family of Finney's mating type 4 has only two offspring, one of which is group *MN* and so cannot contribute to the linkage test. The remaining three families appear in the analysis of Table 1, which follows Finney's scheme.

Table 1

Family	Mating type	*a*	*b*	*c*	*d*	$\lambda = \frac{1}{2}u_{11}$	$K_c = \omega_1$
III (1)	4	2	0	0	0	1·00	1·00
III (5)	4	0	1	3	0	6·00	6·00
III (8)	3	1	0	0	1	1·00	1·00
						$S(\lambda) = 8{\cdot}00$	$8{\cdot}00 = S(K_c)$

$$\frac{S(\lambda)}{\sqrt{S(K_c)}} = \frac{8}{\sqrt{8}} = 2{\cdot}828; \quad P < 0{\cdot}01 \quad (1 \text{ per cent point} = 2{\cdot}33)$$

An attempt has been made to include three 'uncertain' families using Finney's technique for test factors showing dominance, but as some of these families are now part-Maori in origin and the gene frequencies for *M* and *N* are not known for Maoris, the results can be only tentative. However, the significance of the results does not seem to be affected by the inclusion of these families using estimated gene frequencies, and an estimate of the recombination fraction shows that the linkage is close (probably less than 5 per cent).

This pedigree will yield further information during the next ten to twenty years as a number of families too young for any member to have developed polyposis have already been extensively examined for blood group and from time to time they will be examined for polyposis.

Migration of Spleen Cells from Subcutaneous Implantation Sites

PARTICULATE matter and cells injected subcutaneously are normally localized at the site of injection, while the suspending medium diffuses outwards[1]. Exceptional behaviour might be expected of cells from the bone marrow and spleen, however, for these cells can become established in homologous tissues after intravenous injection into irradiated hosts[2]. On the other hand, the intravenous route of injection is more effective than the subcutaneous in procuring the functional survival of these cells, as judged by protection against lethal irradiation[3], and the adoptive transfer of immunity[4]. The continued production of a specific antibody by spleen cells was used in the present experiments, to determine their localization after subcutaneous implantation.

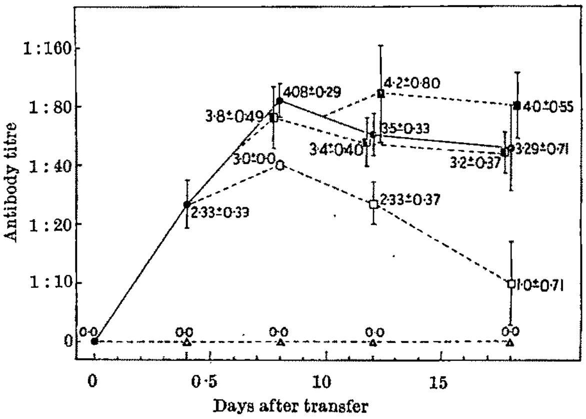

Fig. 1. Antibody titres of sera from host mice after transfer of spleen cells (means with standard deviations from 3–7 mice). Untreated cells, ●——●; subcutaneous site removed on fourth day, □- - -□; subcutaneous site removed on sixth day, ◧- - -◧; subcutaneous site removed on tenth day, ■- - -■; frozen-thawed cells, △- - - △

Spleen cells were transferred from immunized mice of the *CBA* strain into adult non-immunized hosts of the same strain. Immunization was carried out by intravenous injection of *Salmonella typhi* (H), according to Mitchison's procedure[5]. The spleen cells were suspended in saline and injected subcutaneously into the flank, at a dose equivalent to one whole spleen into each host. At intervals after transfer, the *H*-agglutinins in the serum of the hosts were titrated (Fig. 1). One group of hosts received frozen and thawed cells. In the other hosts the cells remaining at the subcutaneous injection site were either removed surgically after an interval, or were left undisturbed.

No antibodies were detected in the hosts after injection of cells that had been frozen and thawed, indicating that no significant quantities of antigen or pre-formed antibody had been transferred with the cells. The appearance of antibodies in the other hosts can therefore be attributed to synthesis by the transferred cells; antibody synthesis occurred, although at a lower level than after transfer of comparable cells by the intraperitoneal route[5]. Removal of the cells at the injection site on the fourth day after transfer was followed by a drop in antibody titre, whereas removal on the sixth or tenth day was without significant effect. It appears, therefore, that functionally active cells were still present at the subcutaneous site up to the fourth day, but that the active cells later migrated elsewhere—presumably into the regional lymph nodes.

Histological examination confirmed the absence of active cells from the subcutaneous site after the fifth day. The remaining lymphoid cells were gradually degenerating and dying, within a well-defined, generally encapsulated nodule. Holub has described similar nodules in the omentum of young rabbits after intraperitoneal injection of lymphoid cells[6].

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer (with a degree in physiology or veterinary surgeon) in the Department of Physiology—The Secretary, Royal Veterinary College, Royal College Street, London, N.W.1 (August 15).

Lecturer in Industrial Administration—The Registrar, Manchester College of Science and Technology, Manchester 1 (August 16).

Assistant Physicist (Basic or Senior grade), for duties concerned with routine radiotherapy physics and the clinical use of radioactive isotopes, with opportunities for research in the clinical application of radioisotopes—The House Governor, Charing Cross Hospital, London, W.C.2 (August 18).

Senior Lecturer (with a university degree, teaching and/or research experience together with a knowledge of tropical soils) in Soil Science in the Department of Agriculture, Kumasi College of Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (August 22).

Lecturer (Grade I or II) in Plant Pathology in the Department of Agriculture, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 25).

Lecturer in Chemistry; and a **Senior Lecturer in Education** at Fourah Bay College (University of Durham), Sierra Leone—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (August 29).

Lecturer in Mathematics (Pure Mathematics) at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 29).

Assistant Lecturer (preferably with an interest in research in the general field of ionized gases) in Physics—The Registrar, University College of Swansea, Singleton Park, Swansea (August 30).

Junior Lecturer in Mathematics—Professor E. C. Titchmarsh, Mathematical Institute, The University, Oxford (August 31).

Physicist, Senior Scientific Officer grade (with a good honours degree in physics, general physical experience, and a knowledge of radiochemical equipment), in the Scientific Branch at County Hall, for research work on properties of materials and in the field of health physics—Medical Officer of Health (PH/D.1/A), County Hall, London, S.E.1 (September 1).

Physicist (with a university degree in science, applied science or engineering, or a technical college diploma or equivalent qualifications and preferably some practical experience in instrumentation, electronics or vacuum techniques) in the Division of Food Preservation and Transport, C.S.I.R.O., Homebush, New South Wales, Australia, to participate in investigations of the relation between the vapour pressure and the water content of biological materials, and in the development and assessment of objective methods for measuring differences in colour between samples of particular foodstuffs—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 300/207 (September 1).

Senior Research Assistant (Ph.D. standard and preferably some experience of electronics and/or low temperature work) in Physics, for a programme of work on the magnetic properties of thin films—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (September 1).

Research Assistant or Junior Fellow in Aeronautical Engineering—The Registrar and Secretary, The University, Bristol (September 8).

Lecturer in Philosophy at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 15).

Students and Fellows, for research in various topics in physical metallurgy, mainly related to nuclear energy, and including irradiation damage, brittle fracture, corrosion of uranium, transformations in uranium alloys, ageing in aluminium alloys, and deformation of semiconductors—Prof. J. G. Ball, Metallurgy Department, Imperial College of Science and Technology, London, S.W.7 (September 19).

Senior Lecturers (2) and a Lecturer in the Department of Biochemistry, University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

Senior Research Officer (graduate, with research experience in amino-acid and protein chemistry) in Biochemistry, to undertake research on the proteins of the wheat grain—The Registrar, University of Melbourne, Carlton N.3, Victoria, Australia (September 30).

Lecturer in Agricultural Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 10).

Research Students and Fellows in Physics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 15).

Assistant Professor or Associate Professor (with a Ph.D. degree in organic chemistry, and preferably research interests in the chemistry of natural products) in the Department of Chemistry—Prof. C. A. McDowell, Department of Chemistry, University of British Columbia, Vancouver 8, B.C., Canada.

Biochemist, for research on problems connected with the composition, enzyme activity and metabolism of healthy and infected leaves at different stages of growth—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Biochemist (preferably with postgraduate experience), for research into lipoprotein metabolism in childhood diabetes—H. B. Salt, Department of Biochemistry, Children's Hospital, Birmingham 16.

Chemical Engineers (with an honours degree or equivalent and significant experience in chemical engineering research), to develop processes and pilot plants in connexion with radioactive substances—Group Recruitment Officer (1179/2), Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Experimental Officer (with a good knowledge of general laboratory technique and experience in the research field) at the Milk Marketing Board's Deep Freeze Unit at Northampton, to be responsible for the handling and freezing of bull semen—The Personnel Officer, Milk Marketing Board, Thames Ditton, Surrey.

Graduate Organic Chemists (2) to join a team investigating a problem in the field of wood chemistry—The Director, Arthur D. Little Research Institute, Inveresk Gate, Musselburgh, Midlothian, Scotland.

Lecturer, Grade B (graduate of a British university), in Mathematics—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11.

Librarian (under 55, with an honours degree in science and preferably some training in geology) in the Geological Survey Department, Federation of Nigeria, for duties which include organizing, indexing and maintaining the Department's library, map collection and technical records; assisting in the collection and abstracting of information on geological research and in the preparation of Geological Survey publications—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/14/010/T.

Mechanical Engineer (professionally qualified and with sound experience in the maintenance and operation of engineering plant and equipment), initially to inspect, accept and commission mechanical plant for the 7 GeV. Proton Synchrotron and, later, to organize and control operation, maintenance and modification of that plant—Group Recruitment Officer (1168/2), Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Research Assistant (physicist, preferably with research experience and a knowledge of electronics), for work on development of methods of temperature measurements in shock tubes—Dr. A. G. Gaydon, Chemical Engineering Department, Imperial College of Science and Technology, South Kensington, London, S.W.7.

Research Assistants in the Department of Chemistry, for experimental work on the thermodynamic properties of mixtures—The Registrar, The University, Reading.

Senior Lecturer (well qualified in physics and prepared to teach to the level of the Diploma in Technology in Applied Physics) in Physics—The Principal, Brunel College of Technology, Woodlands Avenue, London, W.3.

William Dick Chair of Veterinary Surgery—The Secretary, The University, Old College, South Bridge, Edinburgh 8.

Zoologist or Physiologist (graduate), to assist in the British Empire Cancer Campaign research on the biology of cancer, including tissue culture—The Administrative Officer, Mount Vernon Hospital, Northwood, Middlesex.

ACADEMIC AND PROFESSIONAL MOBILITY

THE discussion on academic mobility at the Home Universities Conference last December*, the report of which was published early this year, originated in an inquiry of some members of the Association of University Teachers in 1956, which was briefly described by Dr. C. M. Rigby in opening the discussion. Out of 749 who replied, excluding assistant lecturers, 124 had had no other experience, and 50 of these had graduated in the university in which they were then teaching; 301 had had no experience of teaching in any other university, and of these 116 were graduates of the university in which they were teaching. Only 216 had experience of teaching in one other university, 81 of two other universities, and 27 of three or more other universities. While these figures relate to only about 8 per cent of the total staff of the universities of the United Kingdom, they indicate that possibly half the academic staff of these universities have taught only in a single university and 15 per cent only in the university in which they themselves graduated.

The inquiry thus suggests that university life in Britain is not being enriched by the movement of university teachers from one university to another to the extent that is desirable; indeed, during the discussion, Prof. R. O. Buchanan commented that mobility between Britain and overseas universities is easier and better provided for than mobility within the United Kingdom. He did not, however, suggest that even here the provision is adequate, and Dame Lillian Penson stressed the importance of mobility between the United Kingdom and countries overseas. She believes that we have now reached a very critical stage in the task the universities of the United Kingdom have undertaken since the War in helping to build up new universities in the Colonial and overseas territories. These territories are becoming genuinely independent and need help from Britain more than ever; but it may not be so easy to persuade people from British universities to make their careers overseas. This is partly due to the belief that their services in university institutions overseas will not be required for long, and Dame Lillian pointed out that we have not yet built up sufficiently a system for seconding experienced members of universities to these overseas universities for one or two years.

Dame Lillian's plea is fully endorsed by a relevant passage in the latest report on "The Colonial Territories, 1957–58". Commenting on this situation, Prof. Buchanan remarked on a difficulty which the Advisory Council on Scientific Policy noted in a wider context in its 1956–57 report. Pointing out that young scientists and technologists holding fellowships or studentships in the United States or Canada are discouraged from returning to Great Britain by the practice of requiring them to return for interview if they are to be considered for employment by British firms, the Advisory Council suggested that industry should set up an organization in the United States and Canada to interview graduates on behalf of United Kingdom employers. Prof. Buchanan obviously believes that such a measure would assist the return flow to Great Britain, but he points out that in actual practice the overseas Dominions and the Colonial universities and university colleges themselves get most of their staff from Britain, or from Canada, without local interviews. Instead, they rely on interviews in the country of origin of the candidates by people whose judgment they are prepared to trust. Prof. Buchanan thinks that on the whole the results are no worse than they are in Britain, where the appointing committees are interviewing committees also, and he suggested that the United Kingdom universities would do well to advertise their vacancies not only in the United Kingdom but also over the whole of the Commonwealth and in the United States, and to arrange for local interviewing committees for candidates from areas overseas. The reports of these overseas committees would then be studied in conjunction with the reports of their own interviewing committees on candidates in Britain. Prof. Buchanan recognized what is involved in this suggestion and the risks that would be incurred; but his suggestion of interviewing committees overseas was fully supported by Prof. H. C. Baldry, who was emphatic that this question of interview is at present a major obstacle—so much so that people in university posts overseas normally only move when they come to Britain on sabbatical leave. He also pointed out that the interruption of research involved in moving is serious, and can itself be an obstacle to mobility. The latter difficulty could be minimized to some extent by administrative action; but the importance of academic mobility, particularly in relation to the universities overseas, was well demonstrated in the discussion by the deep appreciation of representatives of such universities in the practical interest of the Conference.

Nor is the interest of the problem limited to the universities themselves. Academic mobility is itself one facet of that interchange of knowledge and culture which is an indispensable element in creative work, the importance of which was stressed by Sir George Thomson in his Fawley Foundation Lecture, "The Strategy of Research", last October. Apart from its contribution to good relations and understanding within and without the Commonwealth, interchange and movement contribute much to the communication of ideas and the stimulation of thought, and we would be wise to foster it as fully as possible.

---

* Report of the Proceedings of the Conference of the Universities of the United Kingdom, convened by the Committee of Vice-Chancellors and Principals, and held in the William Beveridge Hall, University of London Senate House, on 13th and 14th December, 1957. Pp. 111. (London: Association of Universities of the British Commonwealth, 1958.) 5s.

That contribution was brought out incidentally by Prof. A. G. N. Fleur at an early stage in the discussion at the Home Universities Conference; but Dr. R. S. Aitken, vice-chancellor and principal of the University of Birmingham, from a study of data from Birmingham, believes that we may already have as much mobility in the science faculty as is desirable, but that in ten to twenty years time there may be an increase in stability at the expense of mobility unless the universities, in concert, extend to senior lectureships the practice of appointment from outside in preference to promotion already customary by many in connexion with chairs. This point was strongly urged by Prof. Fleur, who also suggested that the Association of University Teachers survey should be extended. We need, he thinks, more detailed information, and while undoubtedly too much mobility can lead to waste, its value in broadening the mind, stimulating experiment and reform and disrupting complacency is undeniable.

It is, of course, true, as Prof. J. L. Montrose remarked, that some of the advantages in mobility could be secured by more exchange in the universities between members of different disciplines; but there is clearly much that could be done by the universities themselves to remove existing hindrances to mobility, many of which, as Dr. Rigby pointed out, are personal or domestic. One difficulty, however, requires wider action, and that is the matter of pension schemes, mentioned by Dr. Rigby but developed more fully by Dr. B. V. Bowden, who referred to the constant interchange of staff between the Manchester College of Science and Technology and industry. This movement is encouraged by all possible means and the College seeks to replace those who leave by people from industry, regarding this as an essential part of the operation of the College. It is important, said Dr. Bowden, that people should come and go between education and industry several times during their professional life, but such interchange is often rendered very difficult by inflexible pension schemes. Representations have been made through the Institute of Actuaries, the University Grants Committee and the Federation of British Industries to try to get something done in the Millard-Tucker Committee, but income tax law makes it extremely difficult for pension schemes to be made portable, particularly in a time of inflation.

Dr. Bowden suggested that the problem deserves much more serious study than it has yet received; but it is also clear that here is one of the points at which Government action could be decisive. Dr. Bowden's remarks also indicated the bearing of academic mobility on the expansion of higher technological education and on education policy generally. He referred specifically to the value of movement not simply between the universities and the colleges of technology and industry but also between the universities and the schools. Factors which hinder movement between the universities and industry can equally hinder the movement between the universities and the schools, and if only for its bearing on the shortage of science teachers, the problem is one that demands the attention of Government in its approach to the expansion of university, technological and technical education.

Academic mobility should not be regarded, in fact, as simply a matter of movement between the universities in the United Kingdom and overseas. It should be considered rather as a matter of promoting the movement of trained men and women, so that they gain the wide experience and varied stimulants they need for the full development of their professional capacity. It should include movement to and from the Government service, the research associations, the technical colleges and industry as well as between universities and the colleges of technology. Upon the care with which it is fostered depends in no small degree the most effective use of the limited resources of trained men and women, and equally the ability to increase these resources both generally and in the particular categories in which they are most urgently needed.

These questions were brought in relation to one particular type of scientific worker in a discussion arranged by the Institute of Biology, a report of which was published in the Institute's *Journal* early this year (see *Nature*, 181, 677; 1958). Dr. E. E. Weatherby's address in particular shows the importance of academic mobility for professional men in general who are seeking service overseas. The matter will require much greater attention than it has yet received before we can hope to find that sufficient numbers of professional men and women are prepared to venture overseas, not merely to serve in universities and other educational institutions but also in other spheres, including the research institutions, many of which are closely linked with the overseas universities and university colleges.

As Dr. Weatherby pointed out, in the re-organization of the Colonial Service the Government has sought to deal with the important issue of security, but only a beginning has been made and much yet remains to be done. Any action the universities may themselves take to encourage academic mobility may well have an effect far outside their walls, particularly in so far as movement to and from the overseas university institutions is concerned; but there are difficulties; notably in security and in regard to pensions, which only government action is likely to solve. Such action is desirable, and indeed imperative, if Britain is to play her full part in assisting the overseas territories to develop their resources and to build up universities and colleges, research institutes and other public services with high standards and great traditions; it is also essential to enable Britain to take a fitting part in technical assistance to the under-developed countries, either under the Colombo Plan or the United Nations. It may equally determine whether we are able to develop what has well been described as our most important and vital export to-day, namely, that of trained man-power, on which will largely depend how far we can make full use of such assets as we possess in nuclear power and like developments.

Ultimately, however, the reason for fostering the movement of trained men and women, between the universities of the United Kingdom and overseas, or between university institutions and industry, the Government service, research institutions, and other walks of life, lies in the contribution it makes to the stimulation of creative thought and the quest for new ideas. Beyond even the contribution to international understanding, this factor is all-important if mankind is to regain control over events. We cannot afford to neglect any means that promise to stimulate creative and imaginative thought, the receptivity to new ideas, sound judgment and the open mind. The expenditure required to remove some of the obstacles is trifling compared with the benefits which the nation and indeed all mankind might well reap, and it is to be hoped that the lead which has already been given will be assiduously followed up by professional associations as well as by the universities and also by such bodies as the Parliamentary and Scientific Committee. At the least, Government policy should be directed towards ensuring that, so far as administrative action can provide, the fullest freedom exists for the contact of trained minds, the communication and discussion of ideas, not only through the printed word but also in those personal contacts which the evidence of the centuries has shown to be so fruitful and stimulating.

RUMINATIONS ON RADAR

Three Steps to Victory

By Sir Robert Watson-Watt. Pp. 480+25 plates. (London: Odhams Press, Ltd., 1957.) 30*s.* net.

THIS book is a combination of an autobiography and a documentary history of the development and applications of radar, intended to clarify the part played by the author and various colleagues. After soliloquizing in an introductory chapter on the theme "Happiness is No Private Enterprise", the book starts somewhere in the seventeenth century and proceeds to beyond 1952 in a final chapter entitled "Happiness in Private Enterprise". But the progress from one end of the book to the other is by no means linear in time. It can be regarded as covering forty years of the author's life, during which the idea of radar was born, forced rapidly through a lusty boyhood, and on to a most vigorous manhood to play its outstanding part in the Second World War and after. The important events are related not in strict chronological sequence, but almost as the author reminds himself of outstanding milestones combined with what many would regard as trivial memories of irresponsible deeds or conversations. We travel backwards and forwards through this period of time in a manner which may not be disturbing to one who, like myself, has lived through the same period and in some sort of touch with the subject. Indeed, having spent almost exactly this period of forty years, oscillating in a very erratic manner between the National Physical Laboratory and the Radio Research Station, where some ten years of the action was played, I found the book of considerable interest. Whether the so-called 'plain man' for whom it is supposed to be written will do so is more questionable; and especially is it doubtful whether the reader of the future, anxious to study the history of the subject, will find it easy to secure an orderly array of the wide range of facts presented to him.

But it is time to tell the reader of this review what the book is about. In the course of seventy-six chapters, and nearly 500 pages, it presents a most attractive and detailed account of the author's reflexions on the outstanding part which radar played in determining the outcome of the Second World War; and for which he and a syndicate of colleagues associated with him received a not inconsiderable financial award. The "Three Steps to Victory" were: first, the instantaneous visual direction-finder developed for locating the sources of atmospherics and belatedly patented by the author in 1924; secondly, the demonstration of radar and its development into a military weapon that revolutionized the art and practice of war in the air, at sea and on the ground; and thirdly, the application of the technique of operational research, which brought the back-room scientist into the planning as well as into the analysis of the day-to-day operations of war.

The main theme of the book is centred around the second of the above items. After preliminary thinking and discussion, a demonstration was given on February 26, 1935, by A. F. Wilkins—the author's closest and most active colleague in all the early work—of the possibility of detecting aircraft by reflexion of radio waves. This experiment was, however, merely to confirm the sound basis of a memorandum entitled "Detection and Location of Aircraft by Radio Methods" which was considered on the following day (February 27, 1935) by the British Committee for the Scientific Survey of Air Defence. This memorandum, which is reproduced as an appendix to the book, is regarded by the author "as marking the birth of radar and as being, in fact, the invention of radar". From this point, the book describes the trials, tribulations and successes which accompanied the conversion of an interesting scientific technique into a practical application, with the tools and equipment placed in the hands of, and entirely operated by, military personnel. The story is told in the author's inimitable style, generally interesting, but sometimes rather involved and not easy to follow. He is naturally reviewing the events with the advantage of his own 'hindsight', but still endeavouring to describe the foresight which was used and applied at various stages of development. Much of the story is supported by references to published and unpublished material, and also to conversations in various high official places. In some cases the speakers who may have commented either lightheartedly or in the heat of an important and urgent discussion may be surprised to find their remarks recorded in cold print.

Chapter 45, with the intriguing title "My Greatest Mistake", explains how the first step—the 'C.R.D.F.' or visual direction finder—was not applied in practice until the middle of the War on account of the pressure of other techniques, followed by the difficulty of making changes once manufacture had started. But the realization that the time of travel of a rocket (*V*2) from firing site to target would be only a few minutes soon brought the 'C.R.D.F.' set out of its 'cold storage'. Another interesting chapter entitled "Hawaiian Week-end" gives a brief account of the Japanese attack on Pearl Harbour on December 7, 1941 (not 1940 as on p. 311), and this is used to illustrate the limitation of the human element in collecting and acting upon information provided by radar. Looking back from the present time, it requires a mental effort to realize the lag of the United States behind Britain in the initial application of radar. As early as the autumn of 1937 it was clearly accepted at the highest professional level that radar was an invaluable and indispensable element in the defence of Great Britain; but four years later the corresponding value and indispensability had still not been recognized in the United States.

To some readers the book may appear to be egotistical; but it is perhaps inevitable that an autobiography must make very frequent use of the first person pronoun. I thank the author for his introduction to a number of unusual words, some of which I found defined in the dictionary; and I was interested to learn that the National Physical Laboratory is an "oddly schizoid institution". The book is a long one for the 'plain man' to read, but perhaps the author's attitude is similar to that of another author (of radio technical books) who once remarked to me: "Maybe there are twice as many words as are necessary, but the reader either gets it that way or not at all". The long text is relieved by a number of most interesting photographs of places and personalities associated with this particular story of radar.

R. L. SMITH-ROSE

NERVES AND MUSCLES

Comparative Physiology of the Nervous Control of Muscular Contraction

By Dr. Graham Hoyle. (Cambridge Monographs in Experimental Biology, No. 8.) Pp. viii+147. (Cambridge: At the University Press, 1957.) 15*s*. net.

THE science of comparative physiology may be said, broadly, to have two objectives. It attempts, on one hand, to describe in an analytical manner the normal working of the variety of animal species, and so to supply evidence, of a different kind from that derived from the study of comparative anatomy, which may help to suggest evolutionary trends. On the other, comparative physiologists attempt, by making use of the variety of physiological processes found in the animal kingdom, to discover the fundamental physico-chemical mechanisms at work in living matter, choosing their material for each investigation so as to take advantage of the peculiar advantages offered by life's variety for the elucidation of its common features.

Dr. Graham Hoyle's monograph on the "Comparative Physiology of the Nervous Control of Muscular Contraction", the eighth in the series of Cambridge Monographs in Experimental Biology, provides an excellent example of an inquiry with the second objective. The field embraced, which is the functional connexion between nerve and muscle, might seem at first sight to be a narrow one; but, as the author points out in his preface, "since a myoneural apparatus is present in all phyla except the Protozoa and the sponges, there is a wide range of animals in which to study the problems". These problems have been intensively studied in recent years in one or two animal types, and a truly comparative review of the whole animal kingdom was certainly called for.

It is taken as axiomatic that the nervous control of muscle *excitation* is an essential stage in the control of muscular *contraction*, and the greater part of the book is concerned with the process whereby the arrival of a nerve impulse at the neuromuscular junction initiates a change in the electrical potential across the surface membrane of the muscle fibre. The full analytical framework used to interpret experiments on neuromuscular physiology is set out about half-way through the book on pp. 67–68. Dr. Hoyle precedes this with one valuable chapter on comparative histology and three on the general biophysics of excitable membranes, which are necessary for an understanding of the myoneural mechanisms. He then goes systematically through the Metazoan phyla, showing how far it is possible to interpret the different mechanisms as variations on the common theme. It could be objected that the framework is derived too largely from detailed studies on the vertebrate and crustacean junctions, and that the provisional assumption that the "broad principles . . . have universal application" is a dangerous one. The immediate answer is that no other analytical framework has yet been suggested, and that it is strength rather than weakness in a hypothesis that it should be clearly stated and be amenable to verification or refutation.

In his last chapter Dr. Hoyle touches on the remaining parts of the control sequence, such as the coupling of muscular excitation to contraction, and the problem of contractility itself. He also discusses the evolution of the myoneural apparatus and mechanisms, and is left with the impression that this has been concerned almost exclusively with modifications of existing parts, the essential features of the architecture and function of the junctions either having reached a satisfactory standard at an early stage, or representing the only possible system. It is, of course, valid to discuss evolutionary trends only in a very broad context of the working of the animal as a whole, and this is only briefly attempted. Within the precise field which it covers this monograph is, however, a valuable addition to the none too plentiful literature on comparative physiology.

J. W. S. PRINGLE

MICROBES AND DRUGS

Ciba Foundation Symposium on Drug Resistance in Micro-Organisms

Mechanisms of Development. Edited by G. E. W. Wolstenholme and Cecilia M. O'Connor. Pp. xii+352. (London: J. and A. Churchill, Ltd., 1957.) 50*s*. net.

Drug Resistance of Microorganisms

By Robert J. Schnitzer and Emanuel Grunberg. Pp. xiv+395. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1957.) 10 dollars.

"CHEMOTHERAPY has still many problems to solve . . . [the greatest perhaps] is how to prevent the rapid development of resistant strains of parasites in relation to the action of specific chemotherapeutic remedies." Thus did Findlay in 1950 express the concern of those whose work is the discovery and development of such agents. Despite the importance of drug resistance and the amount of published work which has appeared, there has been, until now, no text-book available for reference or instruction. Drug resistance has been considered in many surveys of chemotherapy, but these have of necessity covered only the broadest outlines of techniques and results, and even less of the mechanisms of development. The publication of both these books is therefore timely.

It is a disquieting admission that chemotherapy is still, after more than half a century of vigorous life, essentially an empirical science. This fact is probably a constant source of intellectual discouragement to the chemist who may be successful in his search for an effective chemotherapeutic agent but who at the same time has little or no idea of the mode of action of that agent. Such success may also bear little or no relation to the thought that has gone into his research. A further source of discouragement may be the emergence of resistance to an otherwise excellent drug. It is generally felt that the answer to this problem can be found only by biochemists and microbiologists.

For this reason, therefore, the Ciba Symposium on Drug Resistance in Micro-Organisms (Mechanisms of Development) was arranged with participants from America, Europe and the U.S.S.R. The first book under review is the result of this Symposium and contains, as is usual in the Ciba Symposia reports, both original papers and ensuing discussion. The papers, representing the efforts and views of leading workers in this field, cover a very wide range of subjects from the general—Dean and Hinshelwood's "Aspects of the Problem of Drug Resistance in Bacteria" and Demerec's "Genetic Aspects of Drug Resistance"—to the particular—Alexander, Cousens and Stacey's "Reactions of the Mutagenic Alkylating Agents with Proteins and Nucleic Acids". It is invidious, however, to select individual papers—there are eighteen altogether—since the standard is uniformly high and the ensuing discussion controversial and stimulating. There is an understandable tendency, however, to concentrate on the academic rather than the practical aspects throughout; understandable since so little work has been done in the field to deal with the problem of resistance. This is gently pointed out in the final general discussion by Lederberg, whose remarks constitute a crystallization of the more practical issues. The main value of the Symposium seemed to be a reconciliation between the two main schools of thought as to the prime responsibility of genetic mutation rather than phenotypic adaptation for resultant resistance.

The second book is an encyclopædic work on the experimental approach to the study of drug resistance. After a brief but valuable appraisal of the history and various aspects of drug resistance, the authors exhaustively set out the methods used for the production of resistant strains of protozoa, spirochætes and bacteria, and discuss the properties of such strains.

The third and longest section of the book is devoted to mechanisms of resistance with particular emphasis on specificity and cross-resistance. There can be no doubt that a considerable amount of information can be obtained about the mechanism of antimicrobial action of substances from a study of specificity and cross-resistance, and this is well brought out here. Further evidence can be obtained from studies on drug antagonism and synergy; these aspects are also discussed. The brief section on theories of drug resistance describes some of the general hypotheses now in vogue and makes stimulating and thought-provoking reading. This is a book which should be on the desk of every worker in the field of chemotherapy.

I. M. ROLLO

MEDICAL STATISTICS

Manual of the International Statistical Classification of Diseases, Injuries and Causes of Death

Based on the Recommendations of the Seventh Revision Conference, 1955, and adopted by the Ninth Health Assembly under the WHO Nomenclature Regulations. Vol. 1. Pp. xli+394. Vol. 2: Alphabetical Index. Pp. xxvi + 540. (Geneva: World Health Organization; London: H.M. Stationery Office, 1957.) 35*s*. (2 volumes).

CLASSIFICATION, which is fundamental to the quantitative study of any phenomenon, has presented particular difficulties when applied to the study of illness and death. A statistical classification of disease must be of manageable proportions; it must be arranged in such a way that the important disease processes can be examined numerically; it must be designed so that every condition will find a place somewhere; and it must restrict entries to conditions of importance by reason of their frequency or gravity. It differs, therefore, from a medical nomenclature, which should provide a catalogue of terms both detailed and extensive, with an encyclopædic quality which must hinder rather than aid statistical calculation.

But perhaps the greatest difficulty in classifying disease lies in the absence of any unifying system. Any classification is inevitably a compromise between a number of conflicting points of view, of differences of opinion as to etiology, anatomy, clinical features, age, etc. Thus no systematic classification of disease is practicable.

"The medical practitioner may found his main divisions of diseases on their treatment as medical or surgical; the pathologist, on the nature of the morbid action or product; the anatomist or the physiologist on the tissues and organs involved; the medical jurist on the suddenness or the slowness of death; and all these points will deserve attention in a statistical classification." (William Farr.)

Even this does not end nosological difficulties. The classification must also have regard to the variations in medical terminology—as between medical men of different vintage or varying specialities or countries. The neoplasms in Britain and elsewhere are varyingly named according to the view as to the pathological process involved; anthrax in French-speaking countries is a staphylococcal infection of the skin and in English, German and other languages it denotes an infection by *Bacillus anthracis*. So many varieties of clinical description of mental disorders are in use in different countries that no one classification could completely satisfy everyone.

Classification of disease must also be bound by expediency—seeking to fit diseases into a framework which aids comparative measurements. Thus influenza and pneumonia are grouped under diseases of the respiratory system and not under infective diseases, mainly because of their close association with acute upper respiratory infections, so many of which are of unknown etiology. Rheumatic fever, for a like reason, has recently been classified with diseases of the circulatory system—because of the cardiovascular sequelæ of the disease—although as a disease of connective tissue it might stand on its own. Degenerative vascular changes manifest themselves as hypertension, arteriosclerosis, cardiac and renal affections or lesions of the central nervous system—it is mere convenience to include cerebral hæmorrhage under diseases of the nervous system; chronic nephritis under diseases of the genito-urinary system; and hypertension under diseases of the circulatory system —although the pathological processes in the body may not be greatly dissimilar.

It follows from these illustrations of the difficulties to be found in classifying disease not only that international agreement can have been achieved only after long discussion, but also that adjustments to any agreed classification will be made with circumspection and must wait upon advances in medical knowledge which have general acceptance.

The outstanding event in a hundred years of international deliberations on the classification of diseases, injuries and causes of death must be accounted the Sixth Revision which appeared in 1948. This was not only the first with anything like world-wide acceptance, but also it provided the first statistical classification for both morbidity and mortality. The Seventh Revision of the International Lists of Diseases and Causes of Death, resulting from the international conference held in Paris under the auspices of the World Health Organization (February 21–26, 1955), which appears in two volumes (classification and index), has made little change in the 1948 manual. The classification is arranged somewhat eclectically in seventeen main sections: the first consists of well-defined infective agents; then follow categories for neoplasms, allergic, endocrine, metabolic and nutritional diseases, with the remaining diseases classified according to their principal anatomical site—nervous, circulatory, respiratory, digestive, genito-urinary systems, the skin, the bones, and congenital malformations. There are special sections for mental diseases, complications of pregnancy and childbirth, certain diseases of early infancy, senility, etc., and accidents, poisoning and violence. The detailed list (pp. 1–42) consists of 612 categories of diseases and morbid conditions, numbered on a decimal system with three-digit numbers. The first two digits present summarily important groups that are significant, and the third digit represents specific disease entities. Thus under deliveries and complications of pregnancy, childbirth and the puerperium (represented by 640–689) complications of pregnancy begin with the digits 64 and those of the puerperium with 68—nine disease entities under each heading being further represented by a third digit. The tabular list of inclusions (pp. 45–353) gives the framework of the classification and lists the conditions included in each category of the detailed list.

The first volume also includes an account of the international agreement on medical certification and the rules for classification. This is in itself as important as the classification, since it greatly affects the validity of certification and the comparability of results.

The introduction to Volume 1 provides a readable, if rather too brief, account of events leading up to the present position and the particular steps which the World Health Organization is now taking to improve the validity of statistics dealing with sickness and death, including the Expert Committee on Health Statistics, National Committees on Vital and Health Statistics, and the World Health Organization Centre for Classification of Diseases. For more detailed information the reader is referred to other publications in a list of references. These also might be strengthened by reference to other documents. Otherwise the World Health Organization has produced an unexceptionable work of great significance to the measurement of health.

CONTROL AND COMPULSION

Economic Planning by Programme and Control in Great Britain

By Prof. Gilbert Walker. Pp. xii+175 (4 plates). (London: William Heinemann, Ltd., 1957.) 18*s*. net.

PROF. GILBERT WALKER brings together in remarkably small compass the main features of government planning and control in Great Britain during the Second World War and the years immediately following it. The early chapters, comprising about one-third of the book, trace the development of economic thought on the problem of unemployment and poverty, explain the use of social accounts as a tool in making policy decisions, and describe the operation of controls in the mobilization of resources during the War. The remainder of the book is concerned with the planning techniques designed to aid a smooth transition from war-time to peace-time conditions and to avoid the boom and slump which followed the First World War.

An inevitable result of trying to cover such a wide field is that the treatment of certain topics suffers from too much compression. For example, the casual reader of Chapter 2 might conclude that the consequence of an increase in income will be the same whether it arises from increased wage-rates or from increased production. Similarly much benefit would be derived from a short section reviewing the changes which occurred in Britain's position as a result of the War and made the continuance of controls necessary.

The author's assessment of the desirability of economic planning emerges towards the end of the book. Government control is practicable in war-time. But in peace-time:

"Democratic governments, determined to remain within the letter and the spirit of the Western tradition, but bent nevertheless on assuming a deliberate and positive control over the direction and magnitude of economic change, have to find the means, other than compulsion, of ensuring that citizens, obeying whatever impulses may move them, freely choose the courses which correspond to the employment of resources marked out by the planners."

The antithesis between Western tradition and compulsion is a false one. Western democracies have long used compulsion in ordering economic life. That a considerable amount of planning was carried out after the War without active compulsion says a great deal for the flexibility of the plans and the good sense of those responsible for their execution. Powers of compulsion, however, existed and although unused they may well have contributed to the success of the Government's economic policy.

Prof. Walker's publishers state that he has written this work with the object of interesting the wider public; many professional economists also will find most useful and enlightening its descriptions of the mechanism of controls and its assessment of their effectiveness.

NORMAN CUTHBERT

THE RAT

Anatomy of the Rat

By Eunice Chace Greene. (Originally published in 1935 as Volume 27 (New Series) of the Transactions of the American Philosophical Society.) Pp. xi+370 (339 figures). (New York and London: Hafner Publishing Company, 1955.) 25 dollars; £9.

The Genesis of the Rat Skeleton

A Laboratory Atlas. By Donald G. Walker and Zolton T. Wirtschafter. Pp. vi+59 (53 plates). (Springfield, Ill.: Charles C. Thomas; Oxford: Blackwell Scientific Publications, 1957.) 57*s*. 6*d*.

THE "Anatomy of the Rat", by Mrs. E. C. Greene, is essentially an atlas and a text-book in quarto form. The text and illustrations occupy about the same space. When this book appeared in 1935 it provided the most complete account of the anatomy of the rat and was a most valuable supplement to the second edition (1924) of H. H. Donaldson's "The Rat". The latter was a mine of quantitative information, presented in tabular and graphic form, for the weights and dimensions of various parts of the body from birth to maturity. In fact, Donaldson presented more pertinent and accurate data on the rat than was available elsewhere for man. His bibliography extended to about 2,000 references. Since then the number of references has more than doubled, for the Wistar rat was adopted as the favourite child of the experimental psychologists. The rat, particularly the Wistar and the Evans–Long strains, knew on which side his bread was buttered.

"Anatomy of the Rat", long out of print, has been reprinted and is now priced at 25 dollars as compared with 5 dollars in 1935. The minor blemishes of the first edition persist; the usual failure to appreciate the genetive form of Latin and Greek words is as before. The removal of these minor blemishes and a few errors of fact may be looked for when a new edition of the book appears. The only weakness in this best of books is the lack of detailed information on the brain, which has assumed great importance as a result of the work of experimental neurologists such as Lashley in Chicago.

"The Genesis of the Rat Skeleton", by Walker and Wirtschafter, of the University of Oregon Medical School, is an attempt to depict the orderly progression of appearance of centres of ossification by radiographs and photographs of alizarin-stained specimens. Little has been added to the data presented by Donaldson in his second edition of "The Rat" (1924), by R. M. Strong (1925) and by A. B. Dawson (1925–34).

This atlas measures 18 in. × 12½ in. and presents an elegant format and Hollywood calligraphy which is tiring to the eyes, especially for such new words as "Cor*o*coid" and "stern*a*bræ". The radiographs and photographs are not satisfying. Radiographs will not stand photographic enlargement to more than three diameters, as the appearance of the emulsion grain obscures the details of the bony structure.

The portrayal and labelling of the centres of ossification in the skull are inadequate. A prior knowledge of the chondrocranium is essential in order to see how the bony centres arrange themselves in relation to the issuing cranial nerves which maintain a foramen between two or three bony anlage in the skull base. Likewise, the membrane bones appear precociously as two-dimensional unilaminar sheets to guarantee the two-dimensional distribution of the overlying nerves. The absence of any anatomical text is a serious objection to this atlas, for an atlas calls for a system.

H. A. HARRIS

THE HAWFINCH

The Hawfinch

By Guy Mountfort. (The New Naturalist.) Pp. xii+176+8 plates. (London: William Collins, Sons and Co., Ltd., 1957.) 18*s*. net.

VERY much can be learnt by concentrating on a single species of bird and studying every aspect of its life, and in Britain there have recently been several admirable monographs giving the results of such work; of these, the present volume is a fine example. Although an enterprising all-round ornithologist with much else to his credit, the author has for long had a particular enthusiasm for the hawfinch. This has been the more repaying in that the species is one of the least familiar of our not uncommon birds—partly because of its wary and elusive habits, and partly because of its very local and rather erratic distribution. Many years of close observation have now enabled Mountfort to present a fascinating picture.

The hawfinch is notable for its large bill, allied with a massive skull and powerful jaw muscles. This arrangement is related to the habit of cracking cherry stones and olive kernels, a feat which the author's collaborators have shown to involve crushing loads ranging from 60 to 159 lb.—and this in a bird weighing a couple of ounces! It is also a strong flier, capable of an almost vertical take-off and of bursts of speed approaching 40 m.p.h.; the wing area is small relatively to weight, and the beats are rapid.

The species succeeds in combining richly coloured plumage, in both sexes, with a perfected habit of stealthy self-effacement. Yet in its own winter flocks and towards other species it is notably aggressive: one of Eric Hosking's photographs, which are among the illustrations, shows a bird leaping forward with snapping bill to put a much larger mistle-thrush to flight. There is also an elaborate courtship ritual, comprising a number of characteristic attitudes—fluffing of throat feathers, a 'penguin' walk, a deep bow of appeasement, an approach with dragging wing-tips, and a bill-touching ceremony. Also described in detail are the various phases of the nesting season, the song and call notes, the diet and feeding habits, together with distribution and migratory movements in Britain and elsewhere. An appendix by John Barlee deals with the flight.

It is unfortunate that, owing to publication costs, a bibliography of 650 titles could only be deposited.

LANDSBOROUGH THOMSON

Population Redistribution and Economic Growth, United States, 1870–1950

1: Methodological Considerations and Reference Tables. By Everett S. Lee, Ann Ratner Miller, Carol P. Brainerd, and Richard A. Easterlin. Prepared under the direction of Simon Kuznets and Dorothy Swaine Thomas. (Memoirs of the American Philosophical Society, Vol. 45.) Pp. xx+760. (Philadelphia: American Philosophical Society, 1957.) 5 dollars.

THIS massive collection of data forms the first part of a larger study to be prepared under the direction of Profs. Kuznets and Thomas. As the title indicates, its primary function is methodological, and the provision of the basic data. Analysis and theoretical evaluation will have to await the appearance of the second volume in the series. Well over half the present volume consists of reference tables, and there is an explanatory text which shows in detail how the tables have been computed.

The tables treat four principal topics. For each of the 48 States and for the District of Columbia there are comparable series from 1870 to 1950 giving estimates of internal migration, figures relating to the labour force, estimates of manufacturing activity and State income estimates. The amount of detailed statistical work that has gone into the preparation of these figures must have been enormous, and there is no doubt that these tables will form a most important work of reference for anyone working on the history of the American economy. In addition to the topics mentioned, there are figures relating to the rural and urban population of each State, to the agricultural and non-agricultural labour force, the number of manufacturing establishments, total wage bill of employees, income per head in various categories and so on. The limitations of the basic data and the assumptions that have been made in constructing them are fully set out. The editors and authors must be congratulated on their industry and ingenuity, and the publishers on the technical excellence of the presentation.

Collecting, Preserving and Studying Insects

By Harold Oldroyd. Pp. 327+15 plates. (London: Hutchinson and Co. (Publishers), Ltd., 1958.) 25*s*. net.

ENTOMOLOGISTS need a work bringing together techniques of collecting and preserving insects, and this book will fully satisfy them. Collecting should not be an end in itself, but a means of getting to know insects, the first step towards studying their lives and activities. As the applied entomologist knows too well, our knowledge is still pitifully small, and it is to be hoped that this book will succeed in one of its objects, the stimulation of more voyages of discovery.

Its first chapter, "Where to Look", is followed by an account of the important business of first catching your insect, describing the various types of net, light traps and other devices, and there is a section on rearing and breeding. Methods of killing, temporary preservation, and preparation of permanent mounts are explained, together with the examination of specimens, the use and care of microscopes and the photography of live as well as dead insects.

There is a section on identification, a key to the orders of insects, and a general account of the features of each order with appropriate collecting and preservation methods. Also included are chapters on classification and nomenclature, the preparation of papers and illustrations for publication, with a guide to the specialist books and journals. Useful appendixes include a glossary of technical terms, reagents and formulæ and addresses of suppliers. A practical book, well illustrated, simply written and most readable, yet detailed enough to make a permanent work of reference, it will be invaluable alike to beginners and all entomology departments B. D. MORETON

Fruit and Vegetable Preservation Industry in India

(Proceedings of the Symposium held at the C.F.T.R.I., Mysore, on 4th and 5th October 1954.) Pp. xiv+485. (Mysore: Central Food Technological Research Institute, 1956.) Rs. 6; 15*s*.; 2.50 dollars.

THIS book contains a foreword by the Director of the Institute, a list of participants in the symposium, the opening speeches and some 64 papers arranged in eleven sections (covering such varied subjects as raw materials, scientific aspects of preservation, quality control, microbiological problems, additives and preservatives, nutritive value, application of refrigeration, types of containers, plant and equipment, technical information services, etc.). It also reports the final discussion on need for action by the Government in promoting research, the type of research station required and the part the Government should play in establishing factories, together with the recommendations for fostering the industry submitted by the symposium to the Planning Commission and other Government departments.

Few, if any, of the papers contain any original data or observations but some are very useful summaries of existing knowledge. Taken altogether they provide a thorough survey of the state of the development of the fruit and vegetable preservation industry of India, and problems which will have to be faced in its further development. R. G. TOMKINS

Physics for Science and Engineering

By Robert L. Weber, Marsh W. White and Kenneth V. Manning. Pp. vii+617. (London: McGraw-Hill Publishing Company, Ltd., 1957.) 60*s*.

IN this very sound introduction to physics, the first eighteen chapters (roughly one-third of the whole book) deal with the important background work of mechanics and the mechanical behaviour of materials, while about the same space is allotted to electricity and magnetism. The authors set out to train the reader in the methodical solution of problems, paying particular attention to units and significant figures, and set a good example in the many worked exercises in the text. Problems, indeed, make up a fair proportion of the short section on heat; while that on light is quite lavishly descriptive, with some excellent pages on spectra, a chapter on colour which is spread with coloured figures in the text, and some good photographs illustrating polarization effects. Sufficient is said about electronics and nuclear physics for the reader to grasp clearly what these subjects are about; but the really thorough spadework has gone into the two major sections of the book, which will repay an equally thorough reading. Because of the emphasis on instruction rather than description, and the type of exercise given, it is possible to place the standard fairly accurately in terms of teaching in Britain. It is about that of the Advanced level of the General Certificate of Education. G. R. NOAKES

Announcing a New International Journal

Volume 1, Number 1, January 1959

Developmental Biology

Volume 1, 1959, 6 issues, 100s.

Editorial Board:

JEAN BRACHET *Laboratory of Animal Morphology* *University of Brussels* *Brussels, Belgium*	ERNST HADORN *Zoological Institute* *University of Zurich* *Zurich, Switzerland*	PAUL WEISS *Rockefeller Institute for Medical Research* *New York, New York*

Managing Editor:

M. V. EDDS, JR., *Brown University, Providence, Rhode Island*

Consulting Editors:

J. D. BOYD
E. BÜNNING
J. D. EBERT
J. FURTH
P. J. GAILLARD
C. GROBSTEIN
S. HÖRSTADIUS
D. MAZIA
G. MONTALENTI
K. B. RAPER
D. RUDNICK
E. WOLFF
T. YAMADA

The purpose of the new journal *Developmental Biology* is to assemble in one medium papers dealing with development in the broadest sense. It will contain articles bearing on problems of embryonic and post-embryonic development, growth, regeneration, and tissue repair, of both plants and animals. Thus, this new periodical will serve as meeting ground for botanical and zoological approaches, drawing on concepts and techniques of a wide range of disciplines, e.g., biochemistry, biophysics, cytology, microbiology, and pathology. Whatever the organism or the method of study used, the principal criterion of acceptability will be the degree of focus on developmental problems. Articles based on the incidental use of developing systems for other purposes will not be accepted. Fifty reprints of each article will be available free of charge.

Developmental Biology will be an international journal, publishing papers in English, French, or German.

All manuscripts in the English language, and all inquiries regarding editorial policy or the preparation of papers, should be sent to:

DEVELOPMENTAL BIOLOGY
Department of Biology
Brown University
Providence 12, Rhode Island, U.S.A.

Manuscripts in French should be sent to:
DR. JEAN BRACHET

Those in German should be sent to:

Scintillators in 5 forms

Scintillators in five forms are now available from Nash and Thompson Ltd.

CRYSTALS
Anthracene, Stilbene, Diphenylacetylene, in discs and cylinders.

PLASTICS
N.11 and N.11-X-ray, high sensitivity, high transmission polyvinyl toluene based.

LIQUIDS
Ready made, sealed in glass containers to your specification, or as scintipaks.

SCINTIPAKS
Accurately mixed dry constituents sealed in polythene envelopes, ready for dissolving in a suitable solvent as required.

POWDERS
Scintillation purity chemicals for crystal growing experiments, and the manufacture of special scintillators.

Meet Nash and Thompson on the S.I.M.A. Stand at the 'Atoms for Peace' Exhibition, Geneva, September 1st - 14th, 1958.

CHEMICAL ASPECTS OF SELECTIVE TOXICITY*

By Prof. ADRIEN ALBERT

Department of Medical Chemistry, Australian National University, Canberra

SELECTIVE toxicity may be defined as the injuring of one kind of cell without injuring some other kind of cell with which the first is in intimate contact[1]. Thus, in agriculture, it is concerned with ridding crops and seeds of noxious insects and fungi, without causing harm to the higher plants. In veterinary and human medicine it is well exemplified by chemotherapy, which safely rids the host of internal parasites. A more delicate form of selective toxicity is met in pharmacodynamics. Here both types of cell are in the one species, and the task of selective toxicity becomes more difficult. This difficulty is intensified by the necessity of exerting a graded response, and of allowing the cells to recover in the course of time. Thus a patient with insomnia can be put to sleep by a drug which acts on the central nervous system, but the nerve cells which have been poisoned (and poisoned to a predetermined degree) must recover in time for the patient to go to his work next morning.

That selectivity is possible seems to rest on two main principles : (*a*) different kinds of cells exhibit very different kinds of distribution phenomena, and (*b*) the anabolic processes of different cells differ widely (catabolic processes appear rather similar). Whereas detailed knowledge of anabolic differences awaits further work in the field of comparative biochemistry, much is already known about differences in distribution.

When a substance is administered, it has to penetrate at least one semi-permeable membrane before it enters into circulation. Sometimes the substance, as administered, is only a 'pro-drug' which has to be broken down to give the true drug. Examples of this kind are phenacetin, chloral hydrate, pentavalent arsenicals and two of the antimalarials : pamaquin and proguanil. But this seems to be a rare phenomenon, and it appears that most substances act in the form in which they are given.

The circulating drug (and by 'drug' is meant any biologically active substance) then takes part in five other phenomena, to various degrees depending on its nature and on the nature of the cell[2]. It can be stored, excreted, or chemically destroyed ; it can penetrate another semi-permeable membrane, or combine with its receptor. Storage can be useful, as with the antimalarial mepacrine, which is stored in capillaries from which it is released (under mass action conditions) to maintain a therapeutic level in the bloodstream. Examples are also known where storage is wasteful or the drug is entirely segregated on 'sites of loss'[3]. Chemical destruction (detoxication), usually by primitive (not highly specific) enzymes in microsomes[4], takes place by one of seven or eight standard chemical reactions which increase partition coefficients in favour of water so that the penetration of further membranes is diminished. Excretion is usually by the kidney or bile duct in mammals, and these are so constituted that the chemical changes brought about by detoxication greatly increase the excretability of the drug[5].

If, as seems usually to be necessary, the drug has to penetrate yet other semi-permeable membranes before its meets the receptor, the chances of selective toxicity are heightened. Four different types of membranes are distinguished[6,2] : (*a*) where diffusion is regulated by pore-size, (*b*) where a lipoidal layer causes substances to diffuse at a rate proportional to their lipoid/water partition coefficient and excludes the majority of ions, (*c*) where a lipoid anion (for example, oleate) assists the passage of cations, and (*d*) where specific nutrients, particularly anions, are transported (often enzymatically), utilizing energy obtained from the simultaneous oxidation of (for example) glucose. Mixed types of membrane have also been found.

Bearing in mind the various types of membrane made available by different kinds of cells, and the various rates at which a drug, imprisoned within any pair of these membranes, will be subjected to the processes of storage, destruction and excretion, it is easy to see how specificity can be promoted merely by small changes in the rate or equilibrium constants governing any of these processes. To be added to these factors, which in sum govern the rate at which the drug will reach the receptor, is the affinity which the drug has for the receptor.

Receptors, according to Ehrlich[7], are chemical groups containing, perhaps, less than a dozen atoms, which normally perform one of the metabolic duties of the cell : when blocked by the drug they can no longer function and thus the pharmacological effect occurs. At the present time workers tend to equate 'receptor' with the active group of an enzyme.

The combination between drug and receptor seems usually to occur by secondary valencies, namely, hydrogen bonds, ionic bonds and multiple van der Waals bonds. Covalent bonds must be rare because such bonds are seldom easily broken at 20°–37° C., whereas most drug-receptor effects can be terminated by washing with saline. Ehrlich was aware of this distinction when he wrote[8] : "If alkaloids, aromatic amines, antipyretics or aniline dyes be introduced into the animal body, it is a very easy matter, by means of water, alcohol or acetone, to remove all these substances quickly and easily from the tissues". This was in 1898, before knowledge of bond-strengths, -types and -distances became as exact as it is to-day[9].

Nevertheless, a few examples are known of the formation of covalent bonds with receptors, mainly by those drugs which can acylate or alkylate (penicillin, the nitrogen-mustards and the phosphorus anti-cholinesterases), but also by a few substances which become chemically incorporated into vital parts of the cell (for example, *p*-aminosalicylic acid into folic acid, and azaguanine into nucleic acid).

Physiological action is highly dependent upon the finest details of chemical structure. If these details are varied ever so slightly, the degree of action is usually radically changed. For example, both the C-methyl-groups in thiamine are essential for its vitamin action. In synthetic drugs, a similar dependence on minute detail is observed. Thus in benzenesulphonamide (I), an amino-group can be inserted in three different positions : in two of these it gives rise to an inactive substance, but in the other it gives the highly antibacterial substance sulphanilamide[10]. Again, in acridine (II), an amino-group can be inserted in five different positions : in three of these it gives aminoacidines which are almost inert, but in either of the other two it gives a powerful antibacterial[11]. Once again, in quinoline (III), a hydroxy-group can be inserted in seven different positions : in six of these, completely inert substances are created, but in the remaining position a strong antibacterial and antifungal substance is produced.

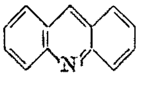
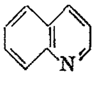
(I)



(II)



(III)

In each of these three examples, it is known why the active isomers are active, and why they alone are the active ones. The activity of the sulphonamides depends on the *para*-isomer being a metabolite analogue for *p*-aminobenzoic acid, to which it shows a close structural resemblance[10]. The activity of the acridines depends upon something quite different : only in the 2- and 5- positions can an amino-group acquire enough resonance stabilization in the cation to produce a highly ionized substance (the antibacterial action of the acridines depends on a high degree of ionization, see below). The activity of the quinolines depends on yet another principle : only in the 8-position can a hydroxy-group collaborate with the ring-nitrogen atom to bind metal cations by that pincers-like process known as chelation, and the antibacterial action of 8-hydroxyquinoline depends upon chelation[12,13].

Since the discovery of the mode of action of sulphonamides, metabolite analogues have received closer investigation and have led to the discovery of many substances which block specific enzymes and hence are of great value to the biochemist. Anti-vitamins, of similar nature, have contributed usefully to nutritional studies[14]. But in human medicine the most successful antimetabolites are, so far, all connected with pteroylglutamic acid (folic acid). This acid, a vitamin or vitamin-precursor, consists of a pteridine nucleus to which are linked *p*-aminobenzoic acid and glutamic acid. Sulphonamides exert their antibacterial action by preventing the incorporation of *p*-aminobenzoic acid into this substance, whereas *p*-aminosalicylic acid actually becomes incorporated in its place. Some antileukæmic agents of clinical value have been made by substituting amino for hydroxyl in the pteridine ring, and a much used antimalarial (pyrimethamine or 'Daraprim') was evolved as a metabolite analogue of the pteridine portion of folic acid[15]. A new type of synergism has been devised, known as sequential blocking, where metabolite analogues of two stages of the folic acid cycle are used together.

The great success of these various anti-folic acid drugs depends on a singular set of coincidences : man does not require *p*-aminobenzoic acid but must absorb folic acid from his diet, and pathogens require *p*-aminobenzoic acid to form their own folic acid, but cannot absorb it if supplied (it is possible, of course, that their folic acid is slightly different from ours). In searching for useful analogues of other metabolites, these facts have to be borne in mind.

The majority of biologically active substances are capable of ionizing to different degrees at different *p*H values ; also the extent of their ionization can be controlled by small alterations in the chemical structure. This variability in ionization is important because an ion and its corresponding neutral molecule undergo different chemical reactions, penetrate membranes differently, and become adsorbed on different types of substance[16]. Because the combination between ions and receptors must be reversible (from the very nature of the bond) the degree of ionization under the conditions of the experiment is all-important for effecting combination. This does not mean, however, that complete ionization is always an advantage, because foreign ions do not readily penetrate membranes ; also, a few examples are known where a pharmacological effect seems to be brought about by the neutral molecule[1,2].

Only two factors affect the degree of ionization of a substance : the ionization constant, and the *p*H at which the experiment is conducted. Given these, the percentage ionization can at once be read from a table[1].

The acridine antibacterials are the most studied example of positive correlation between ionization and biological activity[11]. It was shown, using 107 variously substituted acridines, that at least 50 per cent of the substance must be present as cation to give a significant bacteriostatic effect. This work produced the antibacterial substance, aminacrine, which is now included in the British Pharmacopœia.

Metal-binding substances are of two types, those like 8-hydroxyquinoline (oxine) which bind by chelation (see above), and those like dimethyldithiocarbamic acid which bind without the aid of chelation (these are usually sulphur-derivatives). Biologically, both types act similarly, provided the stability constants are high enough. Stability constants, which are derived from mass-action equations, form a reliable indication of the avidity with which a metal is held by a particular binding agent. Contrary to general belief, the various binding agents show very little differences in their preference for the different metals.

Some metal-binding agents are used in medicine as antidotes to poisoning because they withdraw toxic metals and metalloids. Examples of this kind are dimercaprol (arsenic, antimony and gold), and ethylenediamine tetracetic acid (lead). Others act by forming toxic complexes with such metals of variable valency as are present in the medium. Such a substance is oxine, which does not injure bacteria in the absence of iron[13]. Toxic complexes of this kind appear to initiate oxidative chain reactions, and death occurs very rapidly. Thus, the chelation of a metal of variable valency does not necessarily decrease its biological action, but often increases it. Measurements of oxidation-reduction potentials now in hand should give a better guide to the choice of inactivators.

Several much-used drugs, such as the salicylates, aureomycin, and isoniazide, bind metals at least as strongly as do the amino-acids, and hence could well act by chelation. Some convincing evidence concerning isoniazide has already been obtained. Chelating agents are widely used in crop-protection, for example dimethyldithiocarbamic acid and its derivates, the mode of action of which resembles that of oxine[17].

Toxicity can be brought about in other ways than through covalent bonding, metabolite analogues, ionization and metal-binding. The rupture of cell-membranes, as affected by phenols, quaternary lipophiles and polymixin, has been reviewed recently[18] and shows some selective effects.

The class of substances known as 'depressants' is unique in that the toxic effect is dependent on chemical structure only to the limited degree necessary to make the substance lipophilic enough to reach the central nervous system. Thus the inert gas, xenon, has been successfully used as a general anæsthetic in man[19]. The lack of a dipole moment indicates that this gas acts in the bulk phase rather than by adsorption at a surface. Thus it seems to be merely a diluent separating biochemical components which should react together. The mode of action of all volatile anæsthetics is almost certainly the same as that of xenon, because they all act at those concentrations which produce a standard thermodynamic activity. This was first demonstrated by Ferguson[20], and the anæsthetic activity of xenon was predicted from Ferguson's principle[21], and verified.

This presentation of the phenomena of selective toxicity has necessarily been from the chemical angle. It is put forward in the hope of supplying biologists with a framework which may help to classify results and to suggest new, and often more decisive, experiments.

FORMATION OF A HELICAL STEROID COMPLEX

By Drs. ALEXANDER RICH* and DAVID M. BLOW*

Section on Physical Chemistry, National Institute of Mental Health, Bethesda, Maryland

THE purpose of this communication is to describe the formation of a helical complex of macromolecular dimensions from the bile acid steroid, sodium deoxycholate.

The reaction was first observed when an aqueous solution of sodium deoxycholate was buffered with glycylglycine. Within a few minutes of making up a solution containing 0·1 *M* sodium deoxycholate and 0·1 *M* glycylglycine, unusual changes occur in the physical properties of the solution. There is a large increase of viscosity, and the solution can be drawn out into very long glassy fibres which are stable and dry into clear brittle rods. Soon the solution can almost be lifted clear of its container as a cohesive jelly-like aggregate. It has a mucous-like stickiness when handled. If the solution is allowed to stand, it will eventually form a clear gel which has considerable rigidity.

The complex can be formed most simply by adding acid to an aqueous solution of sodium deoxycholate. The solution becomes very viscous when the *p*H falls below about 6·8 (about 0·2 equivalent of acid). Addition of much larger amounts of acid causes a precipitate of the insoluble deoxycholic acid to form, but there is a range of *p*H and concentration in which the solution is clear and viscous. High ionic strength evidently assists the complex to remain in solution, and solutions of less than 0·01 *M* are always turbid in this *p*H range unless salt is added. The formation of the complex is immediately reversed on raising the *p*H.

By working with these dilute solutions, the phenomenon can be studied in a viscometer. In an aqueous solution containing 0·01 *M* sodium deoxycholate, 0·01 *M* glycylglycine and 0·04 *M* sodium chloride, a maximum viscosity is reached in about 15 min. The macromolecular dimensions of the complex can be demonstrated in the analytical ultracentrifuge, which shows a rapidly migrating peak with a sedimentation constant of 12–15 S. The solutions which have been described as clear always exhibit the Tyndall effect to some extent.

We should explain that we have had some difficulty in finding an adequate terminology for describing these phenomena. The above observations are characteristic of the formation of an elongated polymer. There is no reason to believe, however, that any covalent bonds are formed in this system, and so we have preferred to use the word 'complex'. Although the particles of the complex are of macromolecular size, we have avoided calling them macromolecules.

X-Ray Diffraction Studies

To study the internal structure of the complex, X-ray diffraction studies were carried out on air-dried fibres, some of which contained glycylglycine in addition to the steroid. The fibres are usually glassy clear and brittle, and have weak negative birefringence (– 0·002). The diffraction patterns are unusually detailed. Two characteristic types of diffraction pattern are reproduced in Figs. 1 and 2. Fig. 1 was obtained from a fibre with a glycylglycine : deoxycholate mole ratio of 0·5 : 1. It can be seen that the more intense layer lines are clearly resolved into a series of spots. Heavier exposures show that the weaker lines are also made up of a series of closely spaced diffraction spots. The equatorial spacings correspond to a hexagonal lattice with $a = 39{\cdot}2$ A. The first layer line spacing is 49·2 A.

---

* Now at the Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts.

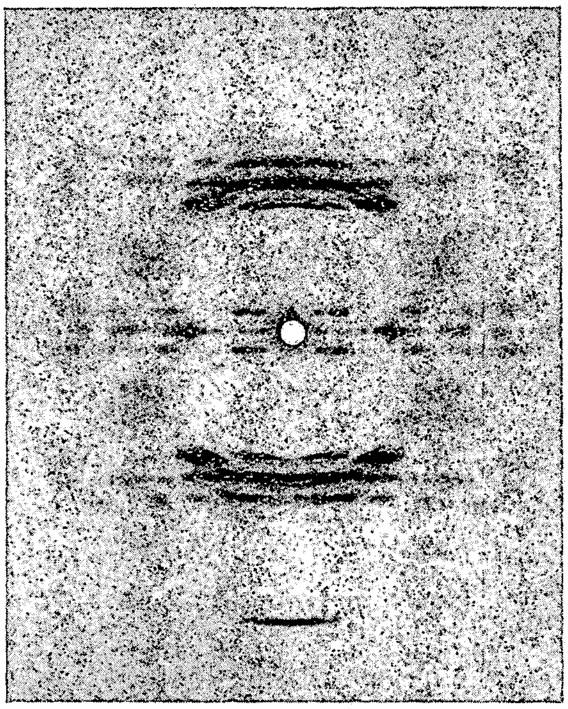

Fig. 1. X-ray diffraction photograph of sodium deoxycholate complex containing 0·5 mole glycylglycine per mole deoxycholate. Fibre axis is vertical, copper $K\alpha$ radiation

Fig. 2 shows a diffraction photograph obtained from a fibre with a glycylglycine : deoxycholate mole ratio of 3 : 1. It can be seen that the diffracted intensity still lies on a series of layer lines with an intensity distribution very similar to that seen in Fig. 1, but instead of resolved spots, a series of continuous streaks appear. This is the continuous Fourier transform and probably arises because individual diffracting units have assumed random angular orientation about the fibre axis and have also undergone some random lateral displacement. The diffraction photograph of a fibre obtained by adding hydrochloric acid to sodium deoxycholate is very similar to Fig. 1, except for changes in the lattice spacings and some intensity alterations described below. Fibre photographs have also been obtained when other amino-acids are used as buffering agents instead of glycylglycine. All these diffraction patterns show similar distributions of intensity, indicating a similar continuous transform which is sampled in different ways, corresponding to different types of crystallinity. For example, in the presence of alanine, the equatorial spacings no longer correspond to a hexagonal unit cell, but indicate another kind of packing. When there is more of the amino-acid component relative to the steroid, the continuous transform occurs more frequently and the structure is less crystalline.

Another important feature of the diffraction pattern is the occurrence of non-integral layer line spacings. Thus, the first layer line in Fig. 1 occurs at 49·2 A. The group of three intense layer lines near the meridian occurs at spacings of 7·65, 6·6 and 5·8 A. These are not integral divisors of 49·2 A. The reason for this discrepancy can be seen more clearly in Fig. 2, where the arrow points to what would normally be called the fourth layer line. It is split into two layer lines which occur at slightly different spacings. Because of this feature[1], and the open areas which occur on the meridian of the diffraction photograph, it is clear that the molecular complex has the form of a helix with a non-integral number of residues per turn[2].

In order to determine the fundamental screw operation which must be carried out to build up the helix from an asymmetric unit, it is necessary to find a true meridional reflexion which represents the translation of the asymmetric unit along the fibre axis. At first it was thought that the 6·6 A. layer line was meridional, but precession camera photographs have shown this to be less likely, and a more probable choice is the layer line which occurs at 2·29 A.

Using this interpretation of the diffraction pattern means that the 6·6 A. layer line represents the pitch of the primitive helix. Hence, we can describe the fundamental screw operation needed to generate the helix as a translation of 2·29 A. and a rotation of $\frac{2{\cdot}29}{6{\cdot}6} \times 360° = 125°$.

An air-dried fibre of the steroid helix formed by adding only hydrochloric acid has a density of 1·19 and a hexagonal a-axis of 36·2 A. (Table 1). These figures can be interpreted as indicating that there are four steroid molecules and approximately twelve water molecules in the asymmetric unit.

The diameter of the helical complex varies with the amount of glycylglycine that is added. Table 1 lists the a-axis of the hexagonal lattice for fibres drawn from solutions with varying mole ratios. Since the complex is helical, the a-axis represents the distance between neighbouring complexes and is therefore its approximate diameter. Table 1 shows

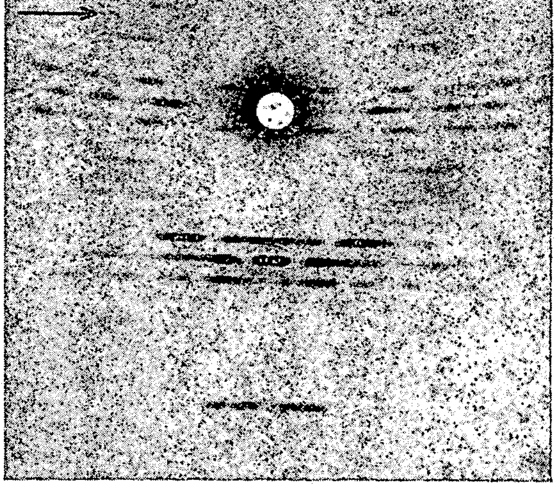

Fig. 2. Diffraction photograph of complex with mole ratio glycylglycine : sodium deoxycholate of 3 : 1. The fibre axis is vertical but tipped slightly. The arrow points to the splitting of the fourth layer line. Copper $K\alpha$ radiation

Table 1. *a*-AXIS OF HEXAGONAL LATTICE FOR COMPLEXES WITH VARYING AMOUNTS OF ADDED GLYCYLGLYCINE

3 : 1	49·1

the composition of the solutions from which the fibres were drawn. Preliminary analyses of fibres have shown that they have the same mole ratio as the parent solutions. Addition of increasing quantities of glycylglycine causes a steady increase of the *a*-axis. The changes show that the excess glycylglycine is incorporated into the lattice. In all the diffraction photographs, the first layer line spacing remains approximately constant at 49·2 A., and the diffraction pattern does not change very much.

On comparing two diffraction patterns with differing amounts of glycylglycine, it was observed that the first layer line at 49·2 A. was more intense near the meridian in the fibre with the large amount of glycylglycine. The increase in intensity occurred at a radius $R = 0\cdot038$ reciprocal units from the meridian. In helical diffraction patterns, the relative intensity on the various layer lines is determined by the magnitude of the *n*th order Bessel functions $\sum_j J_n(2\pi r_j R)$, where r_j is the radius of the j^{th} atom, R is the radius in reciprocal space, and n is determined by a selection rule[2].

If the 2·29 A. layer line is a true meridional reflexion, the selection rule states that the first layer line is composed chiefly of third-order Bessel functions. This may be used to obtain an approximate value for the radius r of the additional glycylglycine. This is done by equating the argument of the third-order Bessel function at its first maximum to $2\pi Rr$, using $R = 0\cdot038$. The answer obtained in this way is 17·6 A. This corresponds closely to the radius of the complex and suggests that at least some of the glycylglycine is packed around the outside of the helical steroid complex. It is quite likely that this explains the occurrence of the continuous transform shown in Fig. 2, since it is more common when there is a large amount of glycylglycine. This component on the outside of the complex may hinder interactions between steroid molecules in adjacent helices and thereby reduce the crystallinity.

It is likely that in the fibres the steroid molecules are built into the helical framework, and at least part of the other component is attached to the outside. This interpretation is supported by the observation that the helical pitch of the complex is independent of the amount of glycylglycine (or of any of the other amino-acids examined). It remains to be seen whether the helical aggregate of deoxycholate molecules will surround itself with other molecules which are incorporated into the lattice as are the glycylglycine residues.

Chemical Properties

Formation of the helical complex is induced by adding protons in the form of hydrochloric acid to an aqueous solution of sodium deoxycholate. This has a considerable influence on the titration curve of deoxycholic acid (3α,12α-dihydroxycholanic acid) as compared to a closely related substance such as cholic acid (3,7α,12α-trihydroxycholanic acid). Cholic acid has a *pK* at 5·5 which corresponds to the titration of the carboxyl group located at the end of the hydrocarbon chain attached to the steroid nucleus. However, under identical conditions (0·1 *M* concentration), deoxycholic acid has a *pK* at 6·6 for the same carboxyl group. The loss of one hydroxyl group located on the steroid nucleus is inadequate to account for the large shift in the *pK* for this group. The explanation is undoubtedly associated with the formation of the helical complex in solution. The deoxycholate ion accepts a proton more readily than the cholate ion in association with its formation into a macromolecular complex. A somewhat similar example of a shift in the *pK* of an ionizable group is seen with polyadenylic acid, where the molecule can be induced to form a macromolecular helix if a proton is added to the adenine residue[3]. The *pK* of adenine has shifted by more than one *pK* unit with its organization into a helical form.

In the deoxycholate complex, it is quite possible that the added proton on the carboxyl group is used in hydrogen bonding to hold together some of the steroid residues. Whether or not all the steroid residues in the complex require a proton remains to be established.

One of the most striking features in the formation of these complexes is the enormous rise in viscosity and eventual gel formation. This must be due to the formation of helical aggregates of considerable length. A helical arrangement of sub-units is, of course, well suited to the formation of very long aggregates, as it can be elongated indefinitely. The extreme length of the particles is probably responsible for the perfection of the diffraction pattern.

A few closely related steroids have been tested to see if they would form similar helical complexes. These include sodium cholate, sodium glycocholate, sodium taurocholate, sodium lithocholate and sodium apocholate. The results were negative in all cases. The formation of the complex is thus highly specific to the geometry of the deoxycholate molecule and can be inhibited by alteration of the hydroxyl positions or by a slight modification of the steroid ring system.

Relation to the Choleic Acids

Wieland and Sorge[4] discovered in 1916 another highly specific interaction in which deoxycholic acid is involved: the formation of the choleic acids. These are crystalline solids, obtained from non-aqueous solutions, in which deoxycholic acid occurs in conjunction with a large variety of organic compounds in definite molecular proportions. The choleic acids formed with long-chain fatty acids have been closely examined and a crystallographic study of their structures was begun by Kratky and his collaborators more than twenty years ago[5]. The only other steroids known to exhibit similar properties are apocholic acid and 'β'-apocholic acid[6], compounds identical with deoxycholic acid except for an unreactive double bond in the steroid ring system.

We are thus confronted by two highly specific interactions in which the deoxycholate residue takes part. It may be helpful to summarize a few profound differences between the two kinds of interaction. The formation of choleic acids is described as an interaction between two types of compound; the complex we have described here forms alone in aqueous solution, and the primary effect is akin to a polymerization. Although the presence of other materials affects the crystallinity and the crystalline lattice of the fibre, this may be regarded as a secondary effect. Indeed, in experiments we have so far carried out, attempting to demonstrate interactions in solution between amino-acids and the complex, we have failed to find any effect. The choleic acids are usually observed in the solid state; in solution they appear only to influence the solubility. This contrasts markedly with the viscosity changes and evidence for formation of large aggregates in solutions of the deoxycholate complex. Finally, we may mention the difference in dimensions between the two. The fatty acid choleic acids crystallize in an orthorhombic unit cell, $P2_12_12$, $a = 25{\cdot}8$ A., $b = 13{\cdot}5$ A., $c = 7{\cdot}2$ A.[5]. This bears no obvious relation to the dimensions of the helix in which the complex forms.

Nevertheless, the two effects probably have some factors in common. Bernal, Crowfoot and Fankuchen[7] have noted that a hydroxyl group in the 3α position of the steroid nucleus is in a specially favourable position for hydrogen bonding. Hydrogen bonding is probably an important force in both effects, and in many other kinds of steroid interaction. What special feature of the deoxycholate molecule confers its unique properties we do not yet know.

We would like to acknowledge assistance and helpful discussion by Mr. K. Shine and Dr. D. F. Bradley, and to thank Dr. Elwood Titus for preparing a sample of apocholic acid.

THE LAST MINUTES OF SATELLITE 1957β *(SPUTNIK 2)*

By D. G. KING-HELE and MRS. D. M. C. WALKER
Royal Aircraft Establishment, South Farnborough, Hants

SPUTNIK 2 made its final descent through the atmosphere between 01.50 and 02.00 hr. U.T. on April 14, 1958, on a line running between New York and the mouth of the Amazon. Though the satellite entered the Earth's shadow before reaching New York, it had by then become self-luminous and a number of valuable observations were made in the Atlantic and Caribbean from ships which happened to be near its track. Observations received from British ships are plotted in Fig. 1, together with two from Trinidad and three 'Moonwatch' observations from near New York.

For the purposes of Fig. 1, the height of the satellite was assumed to vary linearly with latitude between 70 nautical miles at 40° N. and 40 nautical miles at 10° N. This assumption is arbitrary and over-simple, but it seems to fit the facts reasonably well. If these heights were correct, the satellite, or what remained of it, would probably have come to earth just north of the equator. In Fig. 1 the estimated track of the satellite is superposed, assuming the inclination of the orbit to the equator is 65°. Estimates of the time are also given, as ringed numbers.

The appearance of the satellite became more spectacular as it proceeded farther south, and the reports from the different ships agree well, except on the question of colour. At latitude 30° N.

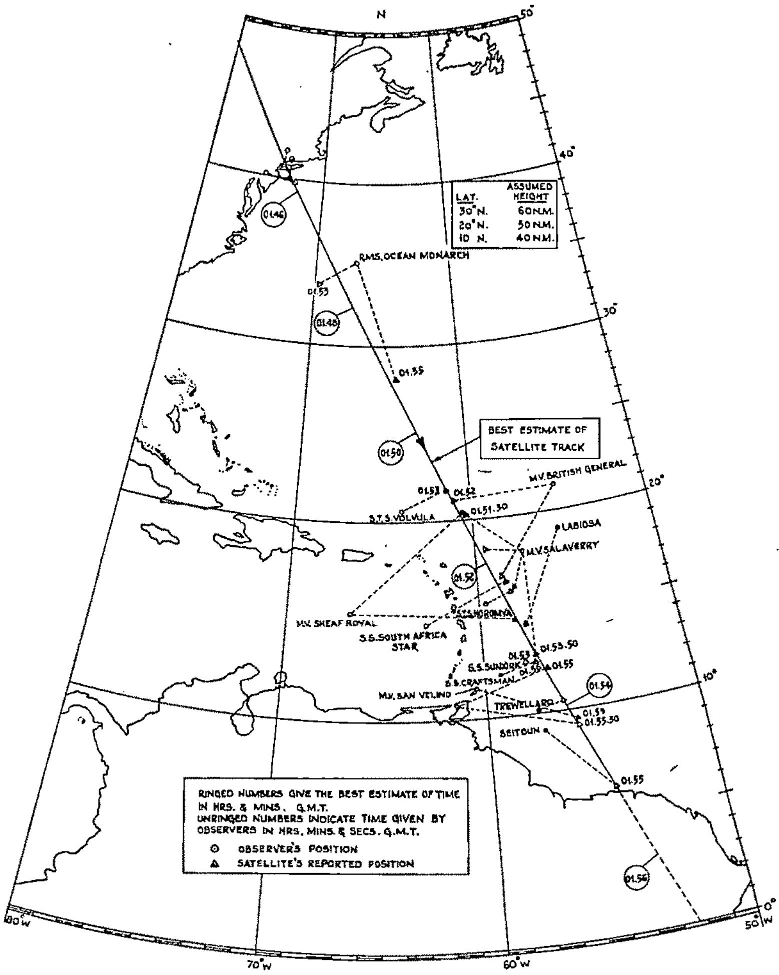

Fig. 1. The last minutes of *Sputnik* 2, April 14, 1958

the satellite was glowing a dull orange, but had developed no tail. At latitudes south of 20° N. it had a long tail alive with sparks, "like those thrown off from a grinding wheel". The sparks were often seen to fall away from the tail and then soon ceased to glow. Estimates of the length of the tail vary between 30 and 90 nautical miles, with a mean of about 50 nautical miles. The estimates of the brightness suggest that when the satellite was between latitudes 20° N. and 15° N. its stellar magnitude was roughly -5 at a distance of 100 nautical miles. The satellite seems to have taken on almost every colour of the spectrum at some time during its descent, and it is only possible to list the colours reported, which were: orange, white, yellow, greenish-blue and red; yellow and orange; orange, silver, blue and green; yellowish-white; blue and red; white to greenish-blue; red and white; green and red; red, orange and white; white; and "a rather sulky crimson".

We wish to thank the captains and crews of the ships from which observations were made. We also thank Mr. D. H. Sadler, superintendent of H.M. Nautical Almanac Office, who arranged for a general call to shipping to be made and sent us the reports received.

OBITUARIES

Dr. W. S. Bauld

THE tragic death of Dr. William St. Clair Bauld, his wife Marion, and two of their children on July 20 in a car accident in Canada profoundly shocked and saddened their many close friends in Great Britain.

Bauld was born at Wolfville, Nova Scotia, in 1919. In 1939 he graduated B.A. with honours in chemistry from Acadia University and then proceeded to Dalhousie University, where he was awarded the degree of M.Sc. in 1941 for research on the œstrogens carried out under the direction of the late Dr. R. D. H. Heard. During 1941–43 Bauld served in the Royal Canadian Artillery and was at first on the teaching staff of the Army Radar School, then becoming overseas liaison officer for the Canadian National Research Council and finally officer-in-charge of inspection of all radar equipment made in Canada. He retired from the Canadian Army with the rank of major.

After the War, Bauld decided to study medicine and enrolled at McGill University. In 1949 he graduated M.D., C.M. I first met Bauld in Montreal a year before his graduation from McGill and was greatly impressed by his personality and by his evident wish to resume research on the œstrogenic hormone. This meeting led to Bauld's appointment to a lectureship in the Department of Biochemistry in the University of Edinburgh in October 1949.

At Edinburgh, Bauld was outstandingly successful both as a teacher and as a research worker. He was a lucid and inspiring lecturer who was very popular with, and respected by, those he taught. His elegant work on the quantitative determination of œstriol, œstrone and œstradiol-17β in urine gained him international recognition as an authority in the field of the œstrogenic hormone, and in 1953 he was awarded the degree of Ph.D. for a thesis embodying the results of this work. A chance observation made by Bauld in the course of this work led to the subsequent isolation by him and me of 16-*epi*œstriol from the urine of pregnant women.

Bauld's contributions to the Edinburgh Medical School were not merely those of a first-class teacher and research worker. His capacity for working hard and playing hard and his infectious enthusiasm for everything he did acted as a tonic to all who came in contact with him. He was greatly missed when he returned to Montreal in 1954 to join the staff of the Montreal General Hospital as an assistant in the Department of Metabolism and Toxicology.

Bauld's progress after his return to Montreal was spectacular. At the time of his death, less than four years later, he had become associate director of the Department of Metabolism and Toxicology, assistant director of the Montreal General Hospital McGill University Clinic and assistant professor of medicine at McGill University, and had become recognized as a chemical pathologist of the highest rank.

The Baulds' home, whether in Edinburgh or in Montreal, was a particularly happy one where visitors were always warmly welcomed. In both cities the Baulds had many friends who loved and respected them and who will miss them sorely.

G. F. MARRIAN

Prof. G. M. Wishart

PROF. G. M. WISHART died on July 18 in his sixty-third year after a short illness. Since 1947 Wishart had devoted himself to administration, being director of postgraduate medical education and dean of the Medical Faculty of the University of Glasgow. Previously Wishart had held the Gardiner chair of physiological chemistry: the later period, given over to administration, has tended to obscure the merit of the scientific work in the earlier years.

The medical profession of to-day accepts with good grace the importance of the basic sciences in the theory and practice of medicine: it was not always so, and men such as Wishart had more than a little to do with this change of heart.

Wishart was instinctively at home in the physical sciences: his first degree was in science; he qualified afterwards in medicine. In the 1920's, biochemistry was applying accurate chemical techniques to biological problems. Wishart studied in Lund under Thunberg and this gave him an abiding interest in the factors governing enzyme action. Hydrogen ion concentration had to be measured accurately because of its importance in biological systems: Wishart designed a glass electrode to measure *p*H. He early appreciated the potentialities of the thermionic valve and designed a most sensitive electronic oscillometer to measure blood pressure in man.

About this same time the application of indirect calorimetry to man had become well established. It was now possible to measure with accuracy the factors, internal and external, influencing the expenditure of energy in human beings. Wishart made a quite exhaustive study of basal metabolism and published a series of papers with a bearing on the metabolic cost of various types of muscular work. Wishart's familiarity with the physical approach to biological problems found expression in 1931 in the publication of a most useful small book, "Groundwork of Biophysics". Yet he did not abandon his interest in more conventional biochemical studies. He took an active part in the work of the Hannah Dairy Research Institute at Ayr and spent several long vacations working in the laboratories there.

During most of this period of fruitful activity, Wishart was Grieve lecturer in physiological chemistry in Glasgow. In 1935 he was elected to the Gardiner chair, and then teaching and administration began to take their toll of his time. All Wishart's work, scientific, academic and administrative, was characterized by meticulous accuracy and by a scrupulously fair presentation of his views. No one better served his University as research worker, teacher and administrator.

R. C. Garry

NEWS and VIEWS

International Co-operation and Geophysical Research

At the recent International Geophysical Year meeting in Moscow, the following resolution was accepted: "The C.S.A.G.I. [Comité Spécial de l'Année Géophysique Internationale] endorses the A.C.I.G.Y. [Advisory Council of the International Geophysical Year] recommendation that observational and data-collecting activities in the geophysical and related sciences be conducted during 1959 on the same general plan as in 1957–58 under the direction of the C.S.A.G.I. or the C.U.R.A.G.I. [Comité d'exploitation et utilization des résultats de l'Année Géophysique Internationale] as far as practicable and at such levels and in such fields as may be determined by each participating committee. The name International Geophysical Co-operation 1959 is suggested for this period". In accordance with earlier decisions, the International Geophysical Year as such will cease at the end of 1958. It was agreed, however, that international co-operation in geophysical research shall continue in so far as each nation finds it practical, and it is left to each nation to decide in which disciplines it shall continue to make observations as during 1957–58 and whether its activity shall be on a higher or lower or at the same level as during 1957–58. The Comité d'exploitation et utilization des résultats de l'Année Géophysique Internationale is a body which will take over from the Comité Spécial de l'Année Géophysique Internationale the work of ensuring international co-operation, and in particular the utilization of the International Geophysical Year results.

California Institute of Technology: Prof. Linus Pauling, For.Mem.R.S.

The resignation of Prof. Linus Pauling as chairman of the Division of Chemistry and Chemical Engineering at the California Institute of Technology is of interest to chemists all over the world. For there can scarcely be any chemist anywhere better known than he. In his books, of which "The Nature of the Chemical Bond" will always remain a classic, and in his 300 research papers, Prof. Pauling has done more than any other person to apply the ideas of the quantum theory to the study of molecular structure. During his tenure of office, the Gates and Crellin Laboratories at 'Caltech' have achieved an almost unique reputation. It was entirely right that he should be elected a Foreign Member of the Royal Society in 1948, and receive the Nobel Prize in 1954.

True to the fate of most pioneers, Prof. Pauling has frequently been at the centre of some kind of controversy. Many people will recall the decision made in the U.S.S.R. some years ago to the effect that his theory of resonance in molecules should be rejected on political and philosophical grounds. Others will think of his difficulties in obtaining a passport from the United States, as a result of the strong opinions which he has courageously refused to disguise. But everyone will be glad that his resignation as chairman is not to imply any diminution of his research interests, for Prof. Pauling will continue in his post as professor of chemistry at 'Caltech'. During the past few years, Prof. Pauling has undertaken fundamental studies of protein structure which are of the highest importance and merit, and show promise of leading to an understanding of the molecular chemistry of such matters as mental disease. In this field his intimate knowledge of molecular geometry and crystal architecture is already showing its tremendous importance. Physicists, chemists and all those who appreciate his warm humanity will wish him well in his newly acquired freedom.

Prof. E. H. Swift

Prof. Ernest H. Swift, who is to succeed Prof. Pauling as chairman of the Division of Chemistry and Chemical Engineering at the California Institute of Technology, graduated from the University of Virginia in 1918. He joined the staff of the California Institute of Technology in 1920 and was appointed professor of analytical chemistry in 1943. As an official investigator for the U.S. Office of Scientific Research and Development during the Second World War, Prof. Swift worked on problems related to the identification of chemical warfare agents and their detection in the field. More recently he has worked on the development of coulometric analysis and is a recognized authority in this field. Prof. Swift is the author of the well-known text-books, "A System of Chemical Analysis for the Common Elements" and "Introductory Quantitative Analysis", and in 1955 he received the Fisher Award of 1,000 dollars given annually in recognition of "outstanding contributions to the science of analytical chemistry, pure or applied, in the United States or Canada".

Botany at Aberystwyth: Prof. L. Newton

Prof. Lily Newton, who is retiring from the Chair of Botany at the University College of Wales, Aberystwyth, began her career as assistant lecturer in the Botany Department, University of Bristol, and in 1920 became lecturer in botany at Birkbeck College, London, under Dame Helen Gwynne-Vaughan. She afterwards worked at the Imperial College of Science and Technology under Prof. V. H. Blackman and her special interest in algæ led her to the position of research worker in the British Museum (Natural History), where she devoted herself to the publication of a comprehensive handbook of British seaweeds. This work was continued after her marriage to Mr. W. C. F. Newton, who was cytologist at the John Innes Horticultural Institution. Following the untimely death of Mr. Newton in 1927, she became lecturer in botany at Aberystwyth and was appointed to the chair in 1930. She was president of Section K of the British Association in 1949, president of the British Phycological Society (1955–57), and while still in charge of the Department of Botany, held the offices of vice-principal and acting principal of the University College of Wales. Prof. Newton has had a distinguished career at Aberystwyth, where she continued the tradition for research on algæ established by the late Prof. Lloyd-Williams. Recently she has developed a fine botanical garden on the new College site. This will be invaluable when the new Department of Botany, which she has also planned, is completed.

Prof. P. F. Wareing

Dr. P. F. Wareing, senior lecturer in the Department of Botany of the University of Manchester, has been appointed to succeed Prof. Newton at Aberystwyth. Dr. Wareing was educated at Birkbeck College and Chelsea Polytechnic, London, while working as a Civil servant, and graduated with honours in botany in 1936. After service as a tele-communications officer during the Second World War, he was appointed assistant lecturer and later lecturer in the Department of Botany at Bedford College, London. In 1950 he moved to the University of Manchester, where he was appointed senior lecturer in 1956. Since 1947 Dr. Wareing has contributed to many important problems in the field of developmental physiology and in particular on the photo-periodic and chemical control of various growth processes. For this work he was awarded the degree of D.Sc.

Psychology at The Queen's University, Belfast: Prof. G. Seth

Dr. George Seth, who has been appointed to the newly created chair of psychology at The Queen's University, Belfast, had already built up there a small but very active Department. Its research output during the past few years has been considerable, and its graduates are already making a worth-while contribution to British psychology. Dr. Seth graduated B.Ed. from the University of Edinburgh in 1930, and thus belongs to the golden age of that degree, when Sir Godfrey Thomson and Prof. James Drever, senior, turned out year after year students who went on to distinguish themselves in education and psychology. Dr. Seth is in fact the eleventh such graduate to be appointed to a university chair. Dr. Seth went up to the University of Edinburgh from the Royal High School, and took his M.A. with honours in English literature. He remained on the staff at Edinburgh, carrying out research for the Ph.D. degree. His thesis was published in 1935 as part of the important study, "Speech in Childhood: its Development and Disorders", by George Seth and Douglas Guthrie. From Edinburgh, Dr. Seth went in 1935 to be lecturer in the Department of Education, University College, Cardiff, where he remained until 1946. In addition to his teaching work, he was psychologist in the Cardiff Child Guidance Clinic, and during 1941–45 psychologist-in-charge of the Psychological Service for Difficult Children (Government Education Scheme) under the Welsh Board of Health. In 1946 he went to take charge of the newly founded Department of Psychology at Belfast. There he has built up a well-balanced teaching and research programme, which has moved out from its beginnings in the vicinity of education to cover the whole psychological field from the experimental to the social boundaries, with applied work in the industrial and clinical as well as the educational fields. The newly created chair does no more than recognize in a fitting way the existence at Belfast of a Department of Psychology well able to hold its own with its older counterparts anywhere in Great Britain.

Control of Research Programmes in the Department of Scientific and Industrial Research

The Council for Scientific and Industrial Research has announced a change in organization affecting the Department of Scientific and Industrial Research laboratories: small steering committees are being set up to bear responsibility for the research programmes at the new Warren Spring Laboratory, at Stevenage, and at the recently renamed National Chemical Laboratory, at Teddington (*Nature*, 182, 156, 225; 1958). Formerly research boards, which the steering committees now replace, were responsible to the Research Council, but there was not necessarily any common membership. Under the new arrangement the steering committees are full committees of the Research Council and there will be a direct link between the two bodies, because the chairmen of the committees are members of the Council. In addition to the chairman there will be four members of each committee: two from industry with experience in research management, the secretary of the Department of Scientific and Industrial Research, and the director of the laboratory concerned. The industrial members of the Warren Spring Laboratory steering committee are Dr. R. Holroyd (deputy chairman of Imperial Chemical Industries, Ltd.) and Mr. D. A. Oliver (director of research of the B.S.A. Group Research Centre). The chairman is Sir Harry Jephcott, who is chairman of the Research Council and chairman of Glaxo Laboratories, Ltd. The industrial members of the National Chemical Laboratory steering committee, which will assume responsibility from October 1, will be Dr. F. Roffey (research and personnel director of the Distillers Co., Ltd.) and Mr. B. Topley (director of development of Albright and Wilson, Ltd.). The chairman will be Prof. C. E. H. Bawn, of the University of Liverpool.

Science Centre Scheme

In a written answer to Lord Bridgeman's request for a statement about the plans for a Science Centre and the reconstruction of the Patent Office, Lord Hailsham said in the House of Lords on July 30 that the Ministry of Works is negotiating for the lease of the site on the South Bank which was designated under the Science Centre scheme for the Patent Office, and it is intended to start building within the next five years. As originally proposed, this building will be designed to accommodate, in addition to the Patent Office, a new National Reference Library of Science and Invention, built up from the existing Patent Office Library. A further review of the original scheme to provide accommodation for the scientific learned societies, at present housed in Burlington House and elsewhere, on a site adjoining that which has now been leased has shown that the needs of the Royal Society and of the other scientific learned societies at present in Burlington House can, for some time to come, be met more satisfactorily in that neighbourhood. Discussions are at present proceeding between the Ministry of Works and the learned societies, and the Government has decided not to proceed with the Science Centre scheme in its original form.

Book Exports

REPLYING to a question in the House of Commons on July 28, Mr. Ian Harvey, Joint Under-Secretary of State for Foreign Affairs, said the Government was seeking to negotiate a British book export scheme with Turkey, and this was under consideration by the Turkish Government. Israel at present allocated some 500,000 dollars a year from its foreign exchange resources for the import of books and periodicals and a proportion of this was spent on imports from the United Kingdom. Indonesian imports were limited by fiscal and exchange controls, but Indonesia was able to include requests for technical books in its requirements for supplies from the United Kingdom under the Technical Co-operation Scheme of the Colombo Plan.

Baghdad Pact Nuclear Training Centre

IN a written answer to a question in the House of Commons on July 28, Commander Noble, Minister of State, stated that from the establishment of the Baghdad Pact Nuclear Training Centre in Baghdad in January 1957 to date Britain had contributed £71,722, of which £23,131 was for initial equipment and freight, £23,421 for the staff from the United Kingdom and £25,170 was towards the annual running expenses of the Centre, including the cost of certain training facilities in the United Kingdom, and of replacement and supplementary equipment.

Academic Administration

AN article in *The Economist* for July 12, entitled "Professors under Pressure", directs attention to the way in which administrative duties interfere with the teaching and research work of professors in large departments which may comprise 200–300 undergraduates, twenty or thirty academic staff and postgraduate students, twenty or more technical and office staff, an annual maintenance budget of perhaps £5,000, and a postal turnover of 4,000–5,000 items a year. The situation is likely to worsen with the increased responsibilities for dealing with new buildings—science blocks, research laboratories, lecture halls and halls of residence—which university expansion must throw on professors over the next ten years. Urging the need for fresh thinking about the organization of the university, both academic and administrative, and for a determined effort to relate the function of a university to its optimum size, and its organization to its function, the article suggests that the head of a large science department should be redesignated 'chairman' and relieved of moral responsibility for teaching and research, the title 'professor' being retained to denote scholarship and research ability.

Protection of Antarctic Fauna

THE need for measures to be taken to preserve birds in the areas of the Antarctic now being visited by man was among other subjects discussed at the Eleventh International Conference of the International Committee for Bird Preservation held in Helsinki in June last. It was agreed by the representatives of twenty countries present to urge that the question of the protection of indigenous fauna, and in particular the much threatened endemic bird fauna, be placed on the agenda of the conference on the future status of Antarctica, for which President Eisenhower and the U.S. Department of State are issuing invitations.

Age Structure in the Engineering Industry

A PRELIMINARY study of age structure in the engineering industry showed that the age of men working at a job is likely to be determined largely by difficulties inherent in the job. This investigation was conducted in the south-west of England. To support the hypothesis that the nature of the work is a major determinant of the age of those engaged in it, similar investigations have been carried out by K. F. H. Murrell and S. Grew of the Unit for Research on Employment of Older Workers, University of Bristol, in other parts of the country (*Occupational Psychology*, 32, No. 2, April, 1958). A number of firms throughout Great Britain were invited by the Institution of Works Managers to submit nominal rolls of their employees. In all, 25 firms, situated in the South Midlands, Yorkshire and Lancashire, and the London region, sent the information required. The nominal rolls included the age and occupation of each man. Although the firms which participated cannot be regarded as a random sample of firms in the engineering industry, they were sufficiently diverse in size, organization and product to be regarded as a fair cross-section of firms in the industry. In no case was the difference in mean ages of a pair of regions significant at above the 5 per cent level. This indicated that the regional samples were likely to have been drawn from the same population, and suggested that there are probably no important regional differences in the age distribution of the working population in the engineering industry. This supports the general conclusion made from the original survey.

Colonial Development Corporation

THE report and accounts of the Colonial Development Corporation for the year ended December 31, 1957 (pp. v+64. London: H.M. Stationery Office, 1958. 4*s*. net), record a net profit of £732,868, compared with £572,809 in 1956, but the net operating profit fell from £371,718 to £227,909. The fall in commodity prices had serious effects, Macalder Nyanza Mines, Ltd. (copper), showing a loss of £207,505. Four projects just coming into production or operation showed losses but should do better on full-scale working: British Honduras Fruit Co., Ltd., Kasungu Tobacco Estates, Vipya Tung Estates, and Nigeria Housing Development Society, Ltd. There are now 76 continuing projects, compared with 66, and three of the ten new projects were on the Corporation's initiative by extension of existing ones; 42 schemes were under investigation at the end of the year and gross new expenditure during the year was £7 million. Commenting on the Overseas Resources Development Act, 1958, which raises the ceiling for the Corporation's borrowing from £100 million to £150 million, the report reiterates that financing of overseas risk-bearing projects solely by repayable loan capital is unsound, and urges as from 1951 a clean start with relief from existing obligations to service capital, and cancellation of equivalent debt to Government, with a note in the accounts recording the writing off of the £8 million. A further reference to the fall in commodity prices emphasizes that this is bound to involve losses in marginal projects, such as those the Corporation necessarily undertakes, and that pressure on Colonial economies has already adversely affected projects which are not themselves primary producers.

International Council of Scientific Unions

The Year Book of the International Council of Scientific Unions of 1958 (pp. ii+74. The Hague: International Council of Scientific Unions, 1958) includes a three-page report, from the Secretary-General, for 1956–57, which records the decision to accept an offer of the Netherlands Government, through the Royal Netherlands Academy of Sciences, to provide a permanent home for the secretariat in the former Royal Palace, Noordeinde, The Hague, and transfer was commenced towards the end of the year. The proposal to publish a quarterly review containing descriptive articles of high standard and details of the current activities of the Unions has been approved by the Executive Board, which has also approved the creation of a Special Committee on Antarctic Research to consider further international organization of scientific activity in Antarctica. Active work in the field of biological abstracting has been organized and at the eighth General Assembly of the Council, to be held at Washington during September 26–October 7, the Executive Board will recommend classification of the International Geographical Union as a General Union. The Year Book is also a work of reference on the Council and the Unions, including lists of members of the Bureau, the Executive Board and the Council, joint commissions, special committees and other organs and of officers of the International Scientific Unions (together with an alphabetical list).

South African Journal of Agricultural Science

The first issue of a new journal devoted to agricultural science in South Africa has recently reached *Nature* office (*South African Journal of Agricultural Science*, 1, No. 1; March 1958. Pp. 108. Pretoria: Government Printer, 1958. 7*s*. 6*d*.). It is evidently designed to cover a wide field, and the six papers in the first issue are concerned with a fungal disease of muskmelon, a disease of citrus caused by mites, the effect on the Argentine ant of application to the soil of chlorinated hydrocarbons, the influence of lime and phosphate on the growth and uptake of blue-bitter lupin, trials of rootstocks for grapefruit, and studies on the biochemistry of cock semen. The papers are in either English or Afrikaans with bilingual titles, and the legends to figures and tables are also in both languages. The summaries are in English, Afrikaans and French. All the papers are of a high standard and the journal is well produced, with some of the plates in colour. This journal will no doubt prove of great value to agricultural scientists in South Africa as a convenient and speedy means of communicating the results of their research.

African Zoological Types

The South African Museums Association has recently published "A List of Zoological and Botanical Types preserved in Collections in Southern and East Africa" (1: Zoology, Part 1. Pp. v+147. Pretoria: South African Museums Association, 1958. Obtainable from the Director, Transvaal Museum, Pretoria. 7*s*. 6*d*.). Its title is self-explanatory: it includes all the types published in the literature up to the end of 1955 that have been traced. The total number is about 5,000, distributed among nineteen institutions and nine private collections. It is to be hoped that provision has been made for the latter to find their way into public institutions, where their accessibility and preservation can be assured. The list does not contain the types of the Karroo reptiles, as these have already been dealt with by Haughton and Brink. The arrangement of phyla, classes and orders follows that in "The Zoological Record", but for convenience in reference, families, species, subspecies and varieties have been arranged alphabetically.

Upper Atmosphere Research in the United States

In Upper Atmosphere Research Report No. 32, February 21, 1958, the U.S. Naval Research Laboratory has given a history of its rocket research programme since 1946 (pp. ii+47. Washington, D.C.: Naval Research Laboratory, 1958. Distributed by U.S. Department of Commerce, Office of Technical Services). Some idea of the extent and scope of the work is indicated by a list of more than 300 publications from the Naval Research Laboratory during this period. The report is a summary of the work carried out and the data obtained from 104 rocket flights. In addition to the scientific data obtained, the instrumentation developed has found application to problems other than upper atmosphere research. Measurements have been made involving the atmosphere, ionosphere, solar and stellar radiation, cosmic rays, air-glow of the night sky, and the Earth's magnetic field. The results achieved are impressive in quality and quantity, although measurements of this type have sometimes revealed inconsistencies indicating the need for further study. An important contribution has undoubtedly been the development of techniques of measurement to an advanced stage, giving reliable operation of measuring instruments in the rocket environment. Of the results obtained, a few examples will illustrate the value of the work. It has been shown that the day-time ionosphere appears to remain dense between the E_1 and F_2 regions, in disagreement with theories suggesting that it is stratified; the F_2 region is much more constant in altitude and lower than previously suggested by ground observations. Measurements with mass spectrometers have given information on the positive- and negative-ion composition of the upper atmosphere, negative ions not being detected on the night flight (115 km.) and positive ions not detected on the day flight (131 km.). The ultra-violet spectrum of the Sun has been studied out to 977 A., a bright emission-line spectrum being photographed in the far ultra-violet. In addition, information has been obtained on the emission of X-radiation. Corrections have been made to the solar constant, resulting in the now generally accepted value of 2·0 cal./min./cm.^{2}. In the northern auroral zone a high intensity of relatively low-energy particles has been detected; these are not protons or heavier particles.

Electronic Temperatures of Planetary Nebulae

Henri Andrillat, of the Observatory at Lyons, has a paper entitled "Les températures electroniques des nébuleuses planétaires" in *Publication de l'Observatoire de Haute-Provence* (3, No. 35; 1957), in which he gives the results of his work on planetary nebulae observable with the 120-cm. telescope at Haute-

Provence. The paper is divided into three parts, the first of which describes theoretical relations between the measurable intensities of the lines and the values of the electronic temperature; and the second deals with electronic temperatures deduced from the intensities of the lines of [O III] measured by the photographic spectrophotometer. Of the two methods mentioned, that using the hydrogen lines allows the extension of the study to fainter nebulae. Twenty-four planetary nebulae were studied and the electronic temperatures obtained ranged between 8,000° and 27,000° K. Comparison of these results with those obtained by others, in particular the photoelectric measurements of Liller and Aller, have led to disagreements which can be explained by taking into consideration the magnitudes of the monochromatic images. From the intensities of hydrogen and helium lines, a correlation is shown to exist between the electronic temperatures and the extent of ionization of the nebula, characterized by the intensity of the helium lines. The third part deals with the continuous spectrum and the Balmer discontinuity of six planetary nebulae, and the experimental results are compared with those of Cillié and of Spitzer and Greenstein. The former give electronic temperatures which are too high, whereas those of Spitzer and Greenstein give temperatures which are too low. Seaton's theory provides results which are in satisfactory agreement, with the exception of N.G.C. 7662, but it is pointed out that his adoption of 13,000° K. for this nebula is inaccurate. It is admitted that, as Seaton has shown (*Mon. Not. Roy. Astro. Soc.*, 114, 154; 1954), it is also possible to compute electronic temperatures starting with the intensities of other forbidden lines.

Space-Group Theory

Of the many X-ray crystallographers who utilize space-group theory in their structure analyses, few have had a systematic training in this theory, and still fewer have read the classical works of Federov, Schoenflies and Barlow in which the 230 space groups are formally derived; most are content to turn to the standard works of reference, such as the "International Tables for X-ray Crystallography", in which the space groups are tabulated without derivation and without emphasis on their interrelationships. In order to meet this difficulty, N. V. Belov published in 1951 (*Trudy Inst. Krist. Acad. Nauk. SSSR*, 6, 25) a 'class-room method' of deriving all the space groups in a systematic manner, based on his teaching experience in the University of Gorkii. This article has now been made available in English in the form of a translation by V. Balashov (*Proc. Leeds Phil. Lit. Soc.*, 8, 1; 1957). Belov's treatment is inspired by the work of Wulff, who directed attention to the fundamental role of planes of symmetry. Starting from this point, Belov derives the 230 space groups, not in the formal sequence of the crystal classes but in an order better adapted to didactic purposes and better suited to bring into prominence the connexions between related groups. The interrelationships of symmetry elements, seemingly so simple, are in fact so subtle that any crystallographer who reads this article is bound to find in it many new ideas and many familiar ideas presented in a new and stimulating guise. The article is an admirable complement to the many other works on space-group theory already available, and its appearance in English translation is most welcome. Offprints of the translation are available at a price of 7*s*. 6*d*. or 1.50 dollars from Austick's Bookshop, 172 Woodhouse Lane, Leeds 2.

Paul Instrument Fund Committee Grants

Awards have been approved as follows: £285 to Dr. J. W. Jeffery, lecturer in physics, Birkbeck College, London, to enable him to carry out crystal structure determination by X-ray diffraction using an instrument for one-dimensional Fourier syntheses employing dekatron counting tubes. £2,000 to Prof. J. D. McGee, professor of instrument technology, Imperial College of Science and Technology, London, to enable him to construct a television system for X-ray image intensification. £11,000 to Dr. V. E. Cosslett, university lecturer in physics, Cambridge, for the further development and improvement of the X-ray microscope: by extending the resolution beyond that of the optical microscope and by attaching an automatic recording mechanism for quantitative analysis of elements. The Paul Instrument Fund Committee, composed of representatives of the Royal Society, the Physical Society, the Institute of Physics and the Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much improved types of physical instruments and apparatus for investigations in pure or applied physical science".

Ramsay Memorial Fellowships Awards

The Ramsay Memorial Fellowships Trustees have awarded fellowships in chemistry for 1958–59 as follows: Mr. G. S. Laurence, a general fellowship at the University of Leeds; a French fellowship to Mme. Mousseron Canet at the Imperial College of Science and Technology, London; a Spanish fellowship to Dr. J. Rodriguez Martinez, at the Atomic Energy Research Establishment, Harwell, and Rothamsted Experimental Station; a United States fellowship to Mr. Phillip G. Thompson at the University of Cambridge. The Trustees have renewed the following fellowships for the same year: Mr. T. E. Peacock (general fellowship) at the University College of North Staffordshire; Dr. D. McK. Wiles (Canadian fellowship) at the University of Leeds; Dr. M. Masui (Japanese fellowship) at University College, London; Mr. J. E. Fergusson (New Zealand fellowship) at University College, London; Mr. P. Arambarri (Spanish fellowship) at Rothamsted Experimental Station; Dr. Diaz Pena (Spanish fellowship) at the University of Reading; Mr. D. Rodriguez (Spanish fellowship) at the University of Sheffield.

Animal Health Trust Awards, 1958–59

The Animal Health Trust has announced the following senior awards for the period 1958–59. *Wellcome Fellowship*: Mrs. H. E. Rose, to investigate the relationship between various members of the Coccidia, using immunological techniques, and to extend the present work on the immune responses of rabbits to *E. stiedae*, to the immune responses, if any, of poultry to their coccidia. This work will be carried out at the Department of Animal Pathology, Cambridge, and afterwards at the Houghton Poultry Research Station, Huntingdonshire. *Research Training Scholarships*: Mr. B. A. Baldwin (Royal Veterinary College, London), to develop methods of assessing the state of consciousness and sensory perception in domestic animals and the physiological aspects of stress associated with the various methods of slaughter of animals ; Dr. A. D. Care, to complete his training for a veterinary degree at the Royal (Dick) School of Veterinary Studies, Edinburgh ; Mr. A. R. Gray, to study the pathology of virus diseases at the Department of Animal Pathology, Cambridge ; Mr. R. F. Sturrock, to study parasitology with special reference to the responses of free-living stages of parasitic nematodes at the Imperial College of Science and Technology, London. Six Evans Final-Year Studentships have also been awarded.

Clayton and Manville Fellowships and Grants, 1958

THE Institution of Mechanical Engineers has made the following awards for special industrial experience, postgraduate studies, or research in mechanical engineering under the terms of the James Clayton Bequest and the Manville Bequest. The total value of the awards is approximately £4,000. *James Clayton Fellowships :* C. R. Evans, for research at the Imperial College of Science and Technology, London, into the stabilization of flames at high speeds ; M. M. Gibson, for research in the University of Liverpool, principally to develop a low-turbulence blower-type wind tunnel for the fundamental study of turbulent boundary layers in two-dimensional flow ; A. F. Pexton, to continue research at the University of Manchester on heat transfer in boiling liquids. *James Clayton Grants :* Dr. M. C. deMalherbe (Johannesburg, South Africa), to visit the United Kingdom to study production methods and for visits to nuclear energy organizations ; D. H. Fleming-Brown (Scotland), to continue studies at Cornell University on reactor containment vessels and on the behaviour of metals at high and low temperatures ; Dr. C. F. Kettleborough (Auckland, New Zealand), to visit British and European universities to study teaching methods, content of courses, laboratory techniques, etc. ; N. Birch (Bristol), to visit the United States to study methods and organization for the manufacture of prototype and aero-engines ; W. H. Emerson, to continue research at King's College, London, on refrigeration ; Dr. J. F. Norbury (Runcorn, Cheshire), to attend the annual meeting of the American Society of Mechanical Engineers to present a paper on fluid mechanics, and for visits to certain universities and research centres in the United States ; *Manville Fellowship :* P. B. Davies, for research at the University College of Swansea on variable-speed transmission of power.

Commonwealth Universities Congress, 1958

THE eighth quinquennial Congress of the Universities of the Commonwealth will be held in Montreal at McGill University and the University of Montreal during September 1–5. Delegations have been appointed by the 109 member universities of the Association of Universities of the British Commonwealth, and the Congress will be attended by 350 members of the teaching and administrative staffs, including 111 delegates from the United Kingdom. The presidents of twenty-seven United States universities and members of the Administrative Board of the International Association of Universities will attend as guests and observers. The opening address, on "Expanding Education", will be given by Sir Hector Hetherington, principal of the University of Glasgow, and at subsequent sessions selected speakers will open discussions as follows : Dr. L. A. Kimpton (chancellor of the University of Chicago) and Dr. V. C. Fowke (Saskatchewan), "Who should determine University Policy ?" ; Prof. J. F. Baker (Cambridge) and Dr. L. A. DuBridge (president of the California Institute of Technology), "Engineering Education and its Place in the University" ; Lord Adrian (vice-chancellor of the University of Cambridge) and Dr. F. G. Soper (vice-chancellor of the University of Otago), "Medical Education and its Place in the University" ; Dr. D. W. Logan (principal of the University of London) and Dr. J. L. Morrill (president of the University of Minnesota), "The Establishment of New Universities". Further information can be obtained from the Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1.

Announcements

DR. S. KRISHNA, scientific adviser in London to the High Commission for India and scientific liaison officer for India, will relinquish his post on August 18. Dr. Krishna's successor has not yet been named ; Mr. B. Sen, assistant educational adviser, India House, Aldwych, London, will be temporarily in charge of the department.

THE British Nuclear Energy Conference, set up in 1955, has increased its membership to nine constituent bodies by the addition of the Joint Panel on Nuclear Marine Propulsion. The Panel consists of four bodies—The Institute of Marine Engineers, The Institution of Naval Architects, The Institution of Engineers and Shipbuilders in Scotland and The North East Coast Institution of Engineers and Shipbuilders.

A CONFERENCE on Gas Discharges, organized by the Physical Society, will be held in the Department of Physics, University College of Swansea, during September 17–20. Further details can be obtained from the Physical Society, 1 Lowther Gardens, London, S.W.7.

A CONFERENCE on Cosmic Rays, organized by the Physical Society, will be held at the Durham Colleges in the University of Durham during September 24–25. Inquiries should be addressed to the Physical Society, 1 Lowther Gardens, London, S.W.7.

A SYMPOSIUM on Cottonseed and its By-products will be held at the Regional Research Laboratory, Hyderabad 9, during December 5–7. Further information can be obtained from the Director, Regional Research Laboratory, Hyderabad 9.

THE eleventh Annual Conference on Electrical Techniques in Medicine and Biology will be held in Minneapolis, Minnesota, during November 19–21. It is sponsored by the Institute of Radio Engineers, the American Institute of Electrical Engineers and the Instrument Society of America through their Joint Executive Committee on Medicine and Biology. Two hundred and fifty-word abstracts for short contributed papers offered for inclusion in the programme can be sent by October 1 to Mr. Robert Erskine, Minneapolis Honeywell, 2753 Fourth Ave. South, Minneapolis, Minnesota, from whom further information can be obtained.

ERRATUM. We regret that in the article entitled "The Structure of Research in Britain" in *Nature* of July 26, p. 207, paragraph 4, penultimate sentence, the word 'not' has been omitted ; the sentence should read, ". . . it would not appear that Treasury control has been exercised in such a way as to infringe the independence or integrity of science . . ."

THE FIFTEENTH INTERNATIONAL CONGRESS OF ZOOLOGY

IT was a happy choice of the Permanent Committee of International Congresses of Zoology to hold the Fifteenth Congress in London during 1958, the same year as the Darwin–Wallace centenary, and in addition the bicentenary of the publication of Linnæus's "Systema Naturæ", 10th edition, the starting point of modern zoological nomenclature. A total of 1,934 enrolments was received, and although approximately two hundred of these were unable to attend, the result was the biggest attendance of any Zoological Congress since they were started in Paris in 1889. The United States, with more than two hundred enrolments, provided the largest overseas contingent, closely followed by France, and there was a large party from the U.S.S.R.; more than sixty countries of the world were represented. The numbers present were much higher than had been anticipated and threw an extra burden on the officers responsible for making the arrangements for meetings, accommodation, excursions, etc. However, the officers, with H. R. Hewer (secretary-general) and N. D. Riley (registrar), proved equal to any emergency. Registration of members and issue of Congress literature, badges, etc., started at noon on July 14. Each member received a copy of the sixth edition of "The Origin of Species" with a preface by Sir Gavin de Beer; and "Evolution by Natural Selection", comprising Charles Darwin's sketch of 1842, his essay of 1844, an introduction by Sir Francis Darwin (1909), Darwin and Wallace's original communication to the Linnean Society on July 1, 1858, the whole with a foreword by Sir Gavin de Beer.

The inaugural plenary session was held in the Royal Albert Hall, where, in the absence of the honorary president of the Permanent Committee, Prof. M. Caullery, whose death was reported during the Congress, the secretary-general, Prof. Louis Fage, introduced the president of the Fifteenth Congress, Sir Gavin de Beer. In his inaugural address, Sir Gavin referred briefly to the events of the past five years, and in particular to the position of the International Commission for Zoological Nomenclature, and paid a tribute to the valuable work of Mr. Francis Hemming, honorary secretary of the Commission during the past twenty-two years, who on the grounds of ill-health had been compelled to offer his resignation. A colloquium had been meeting during the week previous to the Congress, for the purpose of concluding the revision of the Rules of Zoological Nomenclature. These had been discussed at every Congress since the foundation of the Commission at Monaco in 1892, and especially at Paris (1948) and Copenhagen (1953), but a definitive text had not yet emerged. Sir Gavin stressed the necessity of this text being produced as soon as possible, in order to avoid the confusion of names that would inevitably result in its absence. He continued by emphasizing the value of congresses such as this where zoologists of all branches could meet and discuss their various problems, for there was a danger that, with the increase of specialization, workers might get so far out of touch as to be unable to profit from each other's progress. He also directed attention to the platform party, which included not only the officers and members of the permanent committee but also the members of the Darwin and Wallace families and the heads of the institutions having special associations with the lives of Charles Darwin and Alfred Russel Wallace.

Later in the morning the meeting became public and Sir Julian Huxley gave an inaugural lecture entitled "The Emergence of Darwinism". He first dealt with the development of evolutionary biology during 1858–72, when it was in full flower, until the 1890's, when William Bateson began a reaction which lasted nearly twenty years. This was succeeded by the present phase of Neo-Darwinism in which the basic concept of natural selection is related to the facts of modern genetics, ecology and palæontology. He then developed his theory that man is the chief agent for the future of evolution on this planet, and by building on the foundations of Darwinism we could use the evolutionary concept in considering the history and future development of our species. A science of human possibilities was considered necessary to help in guiding the long course of psycho-social evolution that lay ahead.

The sectional meetings started that afternoon and continued until July 23. The programmes were arranged in twelve sections: general zoology; evolution, taxonomy and genetics; marine zoology; invertebrate zoology; vertebrate zoology; comparative physiology; embryology; parasitology; cytology; ecology; animal behaviour; and zoological nomenclature.

An unprecedented number of papers had been presented for communication and many could only be 'read in title', but all those submitted by members of the Congress will be printed in the *Proceedings*. It is invidious to select any particular communication among the hundreds presented, but an exception must be made of a series of papers dealing with *Neopilina galatheae* and the Monoplacophora, comprising an account of the comparative anatomy of this very primitive mollusc by H. Lemche and K. G. Wingstrand, and molluscan phylogeny and prostomal inter-relationships in the light of *Neopilina*, both by H. Lemche.

The programmes ranged over a very wide field: the communication of zoology; the conservation of Nature; the teaching of zoology; the ancestry of man; the physiological basis of sense perception; neurosecretion; hormones; new approaches in cytology; primate behaviour; flight and migration in birds and insects; ecology and behaviour; to mention only a few of the topics discussed.

The meetings were held in the lecture rooms of the Imperial College of Science and Technology and the Memorial Hall of the Royal Geographical Society. The Reception Room and adjoining rooms in the Students' Union provided an extraordinary and valuable range of services.

The main social functions included receptions at the British Museum (Natural History); the Senate House, University of London; and the Zoological Society of London, in its gardens in Regent's Park; also a private reception by the Shell Petroleum

Company. On Sunday there was an orchestral concert in the Royal Albert Hall in which all the items were associated with animals, and the composer of the overture "The Wasps"—Vaughan Williams—happens to be the grand-nephew of both Charles Darwin and his wife. There were also excursions to Down House, Juniper Hall and Whipsnade Park, in addition to long tours after the Congress.

The final plenary session began with two papers, the first by E. N. Pavlovsky on "Some Modes of Evolution of Infections and Parasitic Diseases", with special reference to work in the U.S.S.R.; the second by J. Millot and J. Anthony, "Resultats actuels de l'étude du Coelacanthe *Latimeria chalumnae* Smith, dernier des Crossoptérygiens", comprising the first detailed account of the anatomy of this interesting archaic fish.

Sir Gavin de Beer then presented the recommendations of the Colloquium on Zoological Nomenclature and mentioned that, under present conditions, it is no longer possible to carry on the work of the Nomenclature Commission on an honorary basis. The International Trust for Zoological Nomenclature, now under the chairmanship of Lord Hurcomb, will have a paid secretary, Mr. R. V. Melville, with a secretarial staff, to undertake the heavy work involved in correspondence and publications. It is hoped that the revised rules of Zoological Nomenclature will be issued within six months.

Sir Gavin also submitted a resolution by Section I "That this widely representative meeting of zoologists from many nations participating in the Fifteenth International Congress of Zoology wishes to place on record in Plenary Session the great urgency of safeguarding the fauna and flora of the Galapagos Islands and welcomes the project, initiated by the International Union for the Conservation of Nature, for establishing on the Islands an International Biological Station for research and for assisting the Authorities of Ecuador in the task of conservation, and trusts that every support will be given by all concerned to the early and successful realization of this vital project".

The resolutions were passed with acclamation and it was then announced that the next Congress would be held in the United States during 1963. Various changes in the Permanent Committee were announced: Prof. J. G. Baer (Neuchâtel) was elected president in succession to M. Caullery (deceased); P. Pierre-Grassé (Paris), secretary-general in succession to L. Fage (resigned); C. F. A. Pantin (Cambridge) and B. Rensch (Münster), in succession to E. Hindle and A. Kühn (resigned); and representatives of four new countries were added, P. Sawaya (Brazil), M. B. Lal (India), T. Jaczewsky (Poland) and J. Uchida (Japan). The new Committee also includes V. d'Ancona (Padua), H. Boschma (Leyden), S. Horstadius (Upsala), A. R. Jorge (Lisbon), E. N. Pavlovsky (Moscow), G. G. Simpson (New York), R. Spärck (Copenhagen), V. van Straelen (Brussels) and E. Witschi (Iowa City), who continue to represent their respective countries.

With the words "Little bear now makes way for big bear", Sir Gavin de Beer introduced the new president of the Permanent Committee, the towering Prof. J. G. Baer, of Neuchâtel, who then addressed the meeting, thus concluding a very successful zoological congress.

EDWARD HINDLE

THE NATIONAL VEGETABLE RESEARCH STATION

MEMBERS' DAY

THE founders' meeting of the National Vegetable Research Station Association took place at the Station at Wellesbourne on June 12. The Association, membership of which is open to anyone interested, aims to foster closer contacts between the research staff of the Station and all concerned with the various aspects of vegetable production in Great Britain. Members elected officers to manage the Association's affairs, and after the meeting the party made a tour of the Station, and members of the staff spoke about their work and demonstrated aspects of it in the field.

The Plant Breeding Section showed first-generation breeding material of spring cabbage obtained under a project to develop a dual-purpose variety, able to be used either for greens or as hearted cabbage. Also on view were the winter-hardy survivors of a number of lines of peas derived from crosses of the hardy maple type with some of the non-hardy commercial varieties. This work was being undertaken in an attempt to develop autumn-sown wrinkled varieties to extend the canning and quick-freezing season. Brief descriptions were given of work on the breeding of non-bolting bunching beet and disease-resistant lettuce, on the production of hybrid onions, and on the inbreeding of brussels sprouts.

The parts of the Pathology Section's work which were demonstrated were those dealing with parsnip canker, tomato stem rot (*Didymella*) and the *Ascochyta* diseases in peas. The natural resistance of parsnip varieties to canker was being tested; existing commercial varieties showed little or no resistance, but some new selections were promising. Members saw plots of outdoor tomatoes being prepared for fungicide tests on *Didymella*, following previous work showing that captan and maneb would greatly reduce the severity of attack. Other diseases being studied included big vein and botrytis diseases of lettuce, clubroot of crucifers, silvering of red beet and mint rust.

The Chemistry Section concentrated on aspects of its field work and several long-term experiments on the mineral composition of soil and plant, soil structure, and plant growth were shown. One of these experiments had made it clear that for crops like brassicas with a high nitrogen requirement, inorganic nitrogen was better than organic, and that no practical advantage was to be gained from splitting dressings of inorganic nitrogen. A nitrogen–phosphorus–potassium factorial experiment, now in its fifth year, showed that large differences in the responses of various crops to levels of phosphorus and potassium could occur; thus potatoes and red beet were showing severe symptoms of potash deficiency on those plots which had had none since the experiment began, while cabbage and carrots had not yet shown any such effects. The laboratory work of this section was concerned with the biochemistry of germination and early growth and with the effect of growth-controlling substances on chemical systems.

The calculation of potential evapo-transpiration of a growing crop from meteorological data had been made possible by the work of Penman and others. The Irrigation Section was developing a practical alternative to these calculations for the commercial grower, and showed a gauge which simulated the water-balance of a plant–soil system and allowed the water deficit at any time to be read off directly. The gauge had been found to give better results than other methods currently available to growers. The section also showed experiments designed to detect the existence or otherwise of moisture-sensitive periods in vegetable crops. Such periods had been found to exist in turnips and peas, and knowledge of them was crucial to good irrigation practice.

The Weeds Section was making ecological studies on the weed seed populations in the plots of the long-term manurial and cultivation experiments, and was also studying the dormancy of weed seeds. The successful use of dinoseb (amine) as a residual pre-emergence herbicide for French and runner beans was demonstrated in the field, also a similar use for simazin on sweet corn.

Various aspects of their work on onions were shown by members of the Physiology Section. These included a trial of varieties for their suitability as pickling onions, and experiments on storage-temperate effects with onion varieties used for the production of sets. Fundamental work being done on competition between crop and weed was mentioned, and members saw a field experiment on one of the practical aspects of this work, namely, the timing of early weeding in row crops. Important depressions in final yield in onions had been shown to result from relatively small delays in the first weeding date.

The Entomology Section presented results from studies on carrot fly and cabbage root fly. Existing methods for controlling carrot fly by seed-dressing followed by top sprays were expensive and sometimes gave but partial control of the pest; new methods using the incorporation of insecticides in the soil were being developed, and low rates of aldrin and dieldrin were found to give complete control of both generations for at least two years. Extensive testing had been done on the effect of soil insecticides on the flavour of carrots and had shown that dieldrin in particular produced little or no detectable changes in flavour. Assays of insecticide residues in the field had been started recently, using *Drosophila*; it had been found that from one application of aldrin at 2 lb. per acre four years previously an appreciable quantity still remained in the soil.

Satisfactory methods for the control of cabbage root fly by insecticides were now known, and attention was being concentrated on the ecology of the pest and the predators of its egg and larval stages. This was begun after it had been found that broadcast application of soil insecticides could lead to increased attack by cabbage root fly larvæ. Recent studies showed that some thirty species of insect were predators of the root fly in its early stages and that they could eat 95 per cent of the eggs laid in a season; it was these predators that were being reduced by the broadcast application of insecticides, and the situation illustrated one of the possible dangers in the indiscriminate use of insecticides in the field. Mention was also made of work on lettuce root aphid and on the control of pea moth.

The Statistics Section was concerned with all the mathematical and statistical problems arising in the work of other sections. In particular, results were being accumulated and methods developed for the analysis of plant growth data, with the object of providing more detailed interpretation of long-term field experiments.

J. A. NELDER

THE MECHANICAL ENGINEERING RESEARCH LABORATORY

MORE than 1,700 visitors from industry, universities, technical colleges and other research organizations attended open days at the Mechanical Engineering Research Laboratory on June 4 and 5. All the work at East Kilbride and Thorntonhall was on show and two new laboratory buildings, completed in 1957, were open for inspection for the first time.

The Metrology Building includes a wing, with a floor area of about 6,000 sq. ft., controlled in temperature to within ± 0·1° of the standard temperature of 20° C. This strict temperature control enables full advantage to be taken of the accuracy of the wide range of precision instruments available for checking the dimensional accuracy of engineering components. The metrology section provides a service to other parts of the Laboratory and to industrial firms ranging from the measurement of surface finish to the certification of the accuracy of large gear-hobbing machines. For the latter work, equipment has been developed for the autographic recording of errors in alignment between the hob-saddle motion and work-table axis of hobbing machines; errors in alignment of 0·0001 in. over a machine traverse of 5 ft. can be recorded. The Mechanisms, Engineering Metrology and Noise Control Division is also developing automatic machines for precision measurement. A prototype measuring bench has been designed for recording errors in precision lead screws: a moiré fringe technique is used and pitch errors are recorded to an accuracy of 0·0001 in. The Metrology Building also houses an anechoic chamber in which the noise-generating properties of complete machines and their component mechanisms can be measured. Preliminary tests on commercial bearings and precision bearings of the same nominal size have shown that the former were noisier, that speed was an important factor and that the radial and axial loads had no significant effect on the noise generated.

The new Heat Building is provided with large quantities of electricity, high- and low-pressure steam, and cooling water for heat-transfer research on a substantial scale. One of the aims of the Heat Division is to provide more accurate basic design data for conventional and novel types of heat exchanger and to analyse the performance of industrial heat-exchange equipment. An experimental rig for measuring heat transfer to regenerator matrices has been used to determine the heat-transfer coefficient for the flow of air through a matrix of randomly packed steel balls. The temperature of the inlet air is varied sinusoidally so that the results are in a convenient form for mathematical analysis.

The Heat Division is also concerned with the preparation of consistent tables of the thermodynamic and transport properties of technically important fluids over wide ranges of temperature and pressure. A DEUCE computer has recently been installed, and is being used principally for this work. A start is being made with argon and carbon dioxide, and it is intended to re-calculate the steam tables and extend their range. Most of these tables will be based on existing data, but some experimental determinations of transport properties are being made. An oscillating disk method is being used to measure the viscosity of gases at moderate temperatures, at pressures up to 100 atmospheres.

The Materials Division is concerned principally with fatigue and creep of metals. It seeks, on one hand, to find out more about the stresses to which components will be subjected in service, and, on the other, to obtain a better understanding of how the material will behave under those stresses. An attempt is being made to explain the mechanism of fatigue damage and failure in terms of dislocation theory. Study of the hardening and embrittlement of mild steel caused by low-stress fatigue loading has shown that, in tensile tests subsequent to cyclic stressing, slip was confined to a few planes which had hardened during the cyclic stressing. This is difficult to account for on a random-network dislocation theory, but can readily be explained if the nature of the preparatory slip is an essential feature of the production of dislocation sources.

Measurements of the propagation of fatigue cracks in thin sheets of various metals have shown that, in the early stages, the rate of growth of a crack is proportional to the current length of crack; at very low stresses, however, non-propagating cracks may form. For fatigue tests on large components, such as railway axles, a novel electronic technique has been evolved which enables rotating–bending tests to be simulated without any rotating parts.

The Materials Division's work on creep is concerned with the behaviour of typical engineering materials under complex-stress systems. For constant loading, the relation between creep-rate, stress and time has been established for a range of metallic alloys at various working temperatures. A generalized version of this relation has now been derived for general-loading complex-stress systems, that is, those in which the stresses are varied during the course of a test. Results of these tests have been compared with various mechanical theories of creep; none of them gave predictions agreeing with the experimental data, although the age-hardening and strain-hardening theories gave upper and lower bounds, respectively. For the special case of relaxation (where the total strain remains constant) a reasonably close prediction of the complex-stress relaxation/time curves was given by the age-hardening theory for an aluminium alloy at 200° C. and a magnesium alloy at 50° C.

The Fluids Division is concerned with basic and applied research on mechanical engineering flow problems, particularly those occurring in water-turbines and pumps, valves, fans and compressors, and oil-pressure mechanisms. Flow measurement is essential in all hydraulic work, and improved techniques have been developed for measuring large rates of flow of liquids in pipes. Electronic equipment has been developed to record the rotational velocity of up to twenty-one propeller current-meters automatically. Advantages over conventional chart recording are convenience and the immediate indication of the number of revolutions in a pre-determined time. A new integration technique has been devised for calculating total flow from point velocity readings (derived from current meters or pitot tubes) in a circular pipe; the mean velocity can be determined with at least as great an accuracy from fewer point readings than equivalent methods. Its use will save time and expense, particularly in field trials. In the salt-velocity method the mean velocity is measured by suddenly injecting into the pipeline a quantity of salt solution of higher electrical conductivity than that of the water. Its passage between two downstream positions, a known distance apart, is timed. Here again electronic techniques have been used to increase the sensitivity of the method and also to provide a direct indication of the time interval. Four flow measurement techniques, the current-meter, pitot-tube, salt-velocity and salt-dilution methods, have been tried out simultaneously in a 40-in. diameter pipeline of a Scottish hydro-electric station at flow rates up to 70 cubic feet per second. Results from all methods agreed within ± 2 per cent of the current-meter values, which were taken as the reference.

Research on hydraulic transmissions is also the concern of the Fluids Division. There is a growing realization in industry that the steplessly variable hydrostatic transmission provides the ideal link between an internal combustion engine and the work it has to do. A 15-h.p. pump-motor has been built with the usual reciprocating pistons replaced by reciprocating balls, resulting in an appreciable reduction in cost. It has an overall efficiency of about 80 per cent for speeds between 1,000 and 3,000 r.p.m. A 40-h.p. axial-type pump-motor has been designed, and fitted with instruments to provide basic design information on piston slipper-pads and port-plates.

The Lubrication and Wear Division undertakes experimental and theoretical investigations of the factors affecting the design and operation of all types of bearings. Gas-lubricated bearings have advantages over conventional oil-lubricated bearings for special applications. Investigations of self-acting air-bearings, where the load-carrying film is generated by hydrodynamic action, have shown that with a conventional clearance of 0·001 in., a 1-in. diameter bearing can carry a load of 1 lb. per sq. in. of bearing area for each 1,000 r.p.m. Such bearings have run successfully at speeds up to 100,000 r.p.m.

A clear understanding of the processes of lubrication and wear is essential if machines are to last long enough to give an adequate return for their cost. New methods of reducing wear often depend on a better understanding of the various factors which cause it. Much attention is therefore given to fundamental studies of physical changes in the structure of surfaces when they are deformed by abrasion or other processes.

The manufacture of almost all metal articles involves plastic deformation of the metal. The Plasticity Division's work is directed towards providing a better understanding of the mechanism of plastic deformation so that economies in plant design and more efficient operation may be achieved. When α-uranium is irradiated with neutrons a greatly accelerated creep takes place, even under small loads. The mathematical theory of plasticity has been applied to explain, in detail, the mechanism of this phenomenon in a uranium aggregate, starting from the known crystallographic properties of a single crystal of uranium.

In many metal-working processes the deformation takes place in the presence of hydrostatic pressure which may be considerably greater than the yield stress of the metal. Equipment has been developed for carrying out simple mechanical tests under pressure up to 100 tons per square inch. Tensile tests on various materials under a range of hydrostatic pressures have shown that there is, generally, a marked increase in their ductility as the pressure is increased. With copper, aluminium and cast-iron the increase in ductility is gradual, with zinc and 'Mazak' (a zinc-base alloy) there is an abrupt change from brittle to ductile behaviour for a small change of pressure. The possibility of extruding brittle materials by carrying out the process under high pressure is being examined. R. J. F. FRANKLIN

ACCURATE MEASUREMENT OF THE VISCOSITY OF LIQUIDS

A SYMPOSIUM on the "Accurate Measurement of the Viscosity of Liquids", arranged jointly by the Institute of Petroleum and the British Society of Rheology, was held on June 6 at the Institute of Petroleum, 61 New Cavendish St., London, W.1. It was under the chairmanship of Mr. W. Pohl (chairman of the Lubrication Committee, Institute of Petroleum) and Prof. E. G. Richardson (University of Durham, president of the British Society of Rheology).

The revised standard methods (British Standard 188 : 57 and Institute of Petroleum, 71 : 58) for measuring the viscosity of liquids in C.G.S. units, which incorporate the experience and the results of co-operative experimental work obtained in Britain and other countries during the post-war years, describe a 'step-up' procedure for the calibration of glass capillary-type viscometers, using master viscometers and freshly distilled water at 20·00° C. with an agreed viscosity of 1·002 centipoises (1·0038 centistokes). Dr. R. Roscoe (University of Durham) pointed out in a paper on the determination of viscosity by the oscillating vessel method that further research on accurate absolute methods of viscosity measurement of liquids as standards is desirable, because of the difficulty in the capillary tube method of the elimination of the end correction. The slight inconsistencies in the careful measurements of J. F. Swindells, J. R. Coe and T. B. Godfrey, who found the viscosity of water at 20·00° C. to be 1·0019 ± 0·0003 cP., arise from small differences in the ends of paired tubes. The oscillating vessel method, advocated by Prof. Andrade and A. Chiong, may prove to be better for accurate viscosity measurements. Dr. Roscoe described a series of precise measurements with water, using oscillating vessels, both spherical and cylindrical, supported by a graduated capillary tube so that the water acted as its own thermometer. In this preliminary work a value obtained for the coefficient of viscosity for water at 20° C. was 1·002 5 ± 0·000 5, but an analysis of the sources of error in the results suggests that with fairly simple improvements in technique, for example, using cylindrical vessels and measuring angular velocity rather than amplitude of oscillation, the accuracy of the method, of the order one part in 10,000, could be substantially greater than that obtained in capillary tube measurements.

The measurement of viscosity by means of a vibrating system using an electronic counting technique was described by Mr. M. T. Browne (Imperial College and Queen Elizabeth College, London), who gave the method of calculating viscosity values for water from the logarithmic decrement, the electronic apparatus counting the number of cycles of vibration occurring while the amplitude decreases from one value to half this value.

For oils of higher viscosity the liquid is located on a plane end of the rod. The apparatus is particularly adapted to measure small changes of viscosity.

In a paper on the precise measurement of kinematic viscosity in the petroleum industry, K. A. Lammiman and P. P. Morris (Esso Research Ltd.) described standard instruments and modern equipment involving electronic timing devices, precisely controlled thermostat baths for a temperature-range from − 100° to 200° C. and above, and the technique used for the scrupulous cleaning of instruments by pressure jets of solvents. The authors described methods of measuring viscosity when only small amounts were available; these required the use of the standard miniature British Standard viscometers, torque viscometers such as the plate-cone type, vibrating systems and a comparative method of the rate of descent of an index of oil (0·05 ml.) in an inclined capillary.

Methods of examining opaque oils and fuel oils and their heat pretreatment were also described, as well as semi-automatic methods using viscometers fitted with platinum probes at the fiduciary markings.

During the past two decades industry has become 'shear' conscious mainly in connexion with the requirements of the Armed Services and the automotive industry. At the rates of shear occurring during flow in standard viscometers, the viscosity does not show variations, but at high rates of shear the coefficient of viscosity is no longer a constant. Dr. R. Schnurmann (Esso Research Ltd.) described a jet viscometer in which frictional heating is practically eliminated when a liquid is forced slowly and in individual drops through a narrow streamlined constriction.

By varying the pressure difference across the aperture or the temperature the rate of shear can be altered over a wide range. The kinetic energy correction can be determined experimentally and is smaller by a factor of 2 than for long capillary viscometers, which usually have a length to diameter ratio of 100.

The viscosity of any liquid containing asymmetric molecules can be made to show a temporary viscosity-fall during flow because of molecular orientation in the flow stream. Castor oil, for example, appears to have a constant viscosity coefficient for rates of shear up to 5,000 sec.$^{-1}$ yet at a rate of shear of 250,000 sec.$^{-1}$ its viscosity is reduced by about 25 per cent. The apparent viscosity over a wide range of rate of shear has a falling characteristic with a point of inflexion, the curve bending upward when an appreciable proportion of the pressure-volume energy is converted into kinetic energy and when turbulent flow takes place. The viscosity of a liquid containing large asymmetric molecules, as in an oil thickened with polymer, which has suffered a permanent viscosity loss through severe shearing, is more sensitive to temperature change than that of the liquid at low rates of shear. On the other hand, when a liquid suffers a temporary viscosity reduction its viscosity–temperature coefficient is smaller while a shearing stress is being applied than when the stress has been removed.

The complexity of the flow behaviour of solutions of some polystyrenes at high dilution was emphasized by Dr. P. P. Rutherford (University College of North Staffordshire), who showed that with a capillary-type viscometer anomalous $\eta sp/c$ and ln $\eta r/c$ values were obtained at the highest dilutions. Upswings in the graphs were observed when these values were plotted against the concentration over the range 0·2–0·4 gm. of polystyrene (mol. weight less than 40,000). The concentration at which these upswings occurred depends on the intrinsic viscosity or molecular weight, the temperature and the kind of solvent used. The flow times for the dilute solutions left in contact with powdered glass for several months were found to be almost unaltered, indicating that adsorption effects on the viscometer walls are negligible. Before an explanation of the anomalies is offered further work is necessary not only on viscosity measurements of fractionated polystyrenes of low molecular weight but also by the measurement of light scattering, density and other properties in the low concentration range.

At the first World Petroleum Congress held at the Imperial College of Science and Technology, 1933, the opinion was expressed by Dr. Guy Barr of the National Physical Laboratory that the international standardization of viscosities should be made with viscometers of known characteristics, as these are much less likely to change than standard viscosity oils. This view is at present maintained by both the British Standards and Institute of Petroleum viscosity committees, and in a short report by Mr. W. O. Jennings (National Physical Laboratory) and Dr. E. W. J. Mardles (chairman of the Institute of Petroleum Viscosity Panel) it was shown by results obtained at the National Physical Laboratory that the average change in the constant of four master viscometers over the period 1953–58 was no greater than + 0·01 per cent.

Information from observation books at the National Physical Laboratory indicated the satisfactory working of the standard methods. The report using these results gives the method of establishing a series of reference viscometers on the basis of the agreed viscosity value of water. The accuracy of the method was assessed by cross checking with other laboratories.

The meeting discussed the various factors by which high precision is attainable and in particular the difficulty of using the quadratic equation, $\nu = Ct - B/t$ where ν is kinematic viscosity, C the viscometer constant, t time of flow and B the coefficient of the kinetic energy of efflux, B being known to be variable. The standard methods indicate ways and means of avoiding the use of B or obtaining a working value for it by calculation.

The experimental determination of term B can conveniently be made, as shown in the report, by first obtaining the value for C, using a flow time not less than 1,200 sec.; then, with a flow time of about, but not less than, 200 sec., evaluating B from the equation $B = Ct^2 - \nu t$, where t is the short flow time and C the constant already obtained.

L. A. Steiner (Viscosity Panel, Institute of Petroleum) described a series of experiments showing the variation of the coefficient B under different conditions of experiment. Using sets of viscometers of the same design but with one variant, namely the capillary diameter, the true constants could be ascertained by a graphical method. It was shown that the variation in the coefficient B could be explained partly by end effects, the shapes of the entry and exit ends of the capillary affecting the results; part of the efflux energy is recovered during the filling of the bulb.

The meeting included the exhibition of some new viscometers and equipment, and was concluded by a visit to the viscometry, chronometry and thermometry sections of the National Physical Laboratory on June 7.

E. W. J. Mardles

THE BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

The fifteenth meeting of the Research Panel of the Association was held on June 12, with Dr. G. R. Tristram (University of St. Andrews) in the chair. The meeting was well attended and was followed by demonstrations and discussions in the Association's Laboratories at 2*a* Dalmeny Avenue, London, N.7.

The meeting commenced with a review by Prof. A. Neuberger (St. Mary's Hospital Medical School, London), with the title "General Aspects of the Metabolism of Collagen". Prof. Neuberger outlined the development of the use of radioactive amino-acids in studies of the laying down and turnover of collagen, and the part which the soluble collagens play in this. He also described work showing the inability of an animal to make use of free hydroxyproline (and hydroxylysine) in collagen synthesis, the hydroxyproline being formed at some stage by the hydroxylation of bound proline.

Drs. N. M. Green and D. A. Lowther (St. Mary's Hospital Medical School) gave a paper "Biosynthesis of Collagen", describing their recent researches. In these they have made use of tissue slices obtained from the connective tissue tumour formed when carrageenin is injected under the skin of a guinea pig. Two problems were studied: the first, the conversion of proline into collagen-bound hydroxyproline, and secondly, the precursor relationships between the soluble collagens together with the search for other collagen-like precursors in the cells.

The microtomed tissue slices were incubated in a Krebs medium, which included radioactive proline, for 4 hr. at 37° C. under oxygen. After washing, they were ground and the soluble collagens extracted. The results showed that, in all the purified collagen fractions, the radioactivity of the hydroxyproline was comparable with that of proline, showing that it was derived from the radioactive proline in the medium. In addition, the collagen soluble in neutral salt showed a very much more rapid incorporation of radioactivity than acid-soluble collagen, which in turn showed greater activity than the insoluble collagen. The addition of free hydroxyproline to a culture did not lead to a reduction in the ratio of radioactive hydroxyproline to radioactive proline, while the addition of radioactive hydroxyproline to a medium free of radioactive proline showed no significant incorporation into the collagen. Changes in ratio of specific activities for collagen, hydroxyproline and proline with incubation time, in the presence of radioactive proline, suggest that hydroxylation occurs before incorporation into the protein. Further experiments, in which subcellular fractions were isolated from the tissues, showed that collagens soluble in neutral salt are present in certain fractions. It was suggested that there is a continuous series of collagens of decreasing solubility, of which neutral salt-soluble and acid-soluble collagens are two arbitrary fractions.

A lively discussion followed the paper, and a vote of thanks was proposed by Mr. S. Henson (William Oldroyd and Sons, Ltd.) and seconded by Dr. J. E. Eastoe (Royal College of Surgeons).

A number of analytical techniques were included in the demonstrations at the laboratory. In each instance, part or the whole of the determination was carried through for each group of visitors. Mr. A. A. Leach described his modified Neuman and Logan technique for hydroxyproline determination. Mr. W. G. Cobbett and Dr. A. W. Kenchington demonstrated tyrosine estimation by ultra-violet absorption and by a modified colorimetric method. Dr. G. Stainsby showed how the biuret method could be applied to estimating gelatine concentrations, and Mr. J. T. Taylor carried out the Kodak test for the setting time of a gelatine solution. Mr. A. M. Kragh showed the powerful action of gelatine and glue as flocculation and filtration aids, when used in the correct conditions.

Much interest was aroused by the demonstration by Dr. A. Courts of the properties of a form of soluble collagen which can be isolated from collagenous tissues after they have received pretreatments of the type used in gelatine manufacture (for example, a cold alkaline soak). Substantial percentages of the collagen could be solubilized in this way using 0·1 *M* citric acid as solvent. The solution was very viscous but, on warming to 43° C., a rapid conversion to gelatine occurred, and the viscosity fell more than 40-fold to a normal value for gelatine. It was possible to precipitate the soluble collagen as fibre by the same procedures as applied to acid-soluble collagens from native tissues. It appears clear that bonds formed when the collagen became insoluble have been broken, enabling the original structural units to be dissolved.

Also on show were equipment for fractionation (W. B. Langston), small-scale gelatine extraction (F. W. Wainewright and A. P. Williams), and the use of *XE* 97 resin for the separation of gelatine components by the method of G. E. Russell (Ilford, Ltd.) (A. A. Leach). A. G. Ward

NUMERICAL WEATHER FORECASTING

THE methods of numerical prediction by electronic computer of the atmospheric pressure field now being investigated are based on finite difference approximations to the differential coefficients in the equations of motion. It is required to forecast the variation with time of the height h of an isobaric surface, and the differential coefficients of this quantity occur in the equations.

Starting with a set of values of h at the grid points of a map, the finite-difference approximations can be computed from more than one set of combinations of the values. The effects of using different combinations have been examined in the numerical forecasting research unit of the Meteorological Office, and the results are published in a recent paper entitled "Experiments in Numerical Integration", by E. Knighting, D. E. Jones and Mavis K. Hinds (*Quart. J. Roy. Meteor. Soc.*, 84, 91; 1958).

The quantities which have to be computed are the Laplacian $\frac{\partial^2 h}{\partial x^2} + \frac{\partial^2 h}{\partial y^2}$ and a Jacobian $J(h,\zeta)$, where ζ is the vertical component of the vorticity, which in turn is expressed as a function of the Laplacian.

The grid points are arranged in square sets. One basic set of grid points is that of the eight points at the centre, corners and mid-points of the sides of a square. These are numbered 0 at the centre, 1, 2, 3, 4 at the mid-points of the sides—with the easternmost point of this set 1, northern 2 and so on counter-clockwise—and 5, 6, 7, 8 at the corners—with the north-east point 5 and the north-west point 6 and so on as before. Then one finite-difference approximation to the Laplacian is:

$$(h_1 + h_2 + h_3 + h_4 - 4h_0)/a^2$$

where h_i is the value of h at point i and $2a$ is the length of a side of the square. Another approximation is:

$$(h_5 + h_6 + h_7 + h_8 - 4h_0)/2a^2$$

Similar, more elaborate combinations apply to the Jacobian.

The authors describe the results of using these different combinations on actual meteorological situations, one of which is the great north-westerly gale of January 31, 1953, which led to the North Sea floods of the following night. Considerable differences are found to occur between the maps of the predicted pressure distributions according to the particular combinations employed. These differences occur even in the centre of the large area dealt with, though that is the part in which, because of its distance from the edges with their specified boundary conditions, errors are usually smallest. The difference between two combinations was about 40 per cent of the actual change in two cases and 10 per cent in a third.

These are serious differences, and the authors point out that on some occasions the choice of a geometrical method of making the finite difference approximations has a decisive effect on the forecast. The differences are believed to be associated mainly with the Jacobian, and the authors consider the remedy will have to be sought by using more complicated finite-difference approximations for the derivatives. This would, of course, mean greater complexity and time in the computation.

RIBONUCLEIC ACIDS IN LIVER CYTOPLASM

By Dr. E. REID and BARBARA M. STEVENS

Chester Beatty Research Institute, Institute of Cancer Research : Royal Cancer Hospital, London, S.W.3

STUDIES in this laboratory on cytoplasmic ribonucleic acid, as influenced by induction of liver tumours[1] or by a change in hormonal status[2-4], have emphasized the need for closer study of the ribonucleic acid in the microsomal and supernatant fractions obtained from normal liver. Microsomal ribonucleic acid and supernatant-fraction ribonucleic acid may differ in function[4,5]; they undergo different changes after adrenalectomy[2-4], and differ in the time of maximum labelling after injection[4] of orotic acid-6-^{14}C [4]. Labelling data[4] were compatible with, but did not prove, the postulate[7,8] that microsomal ribonucleic acid is derived from ribonucleic acid in the supernatant fraction. Supernatant-fraction ribonucleic acid might be derived from acid-soluble nucleotides rather than from nuclear ribonucleic acid[9,10], but no evidence to support this possible relationship emerged from a comparison of the labelling of acid-soluble uridine nucleotides with that of cytoplasmic ribonucleic acid, after injection of labelled orotic acid[6].

The study of precursor-product relationships *in vivo* is hampered by the apparent heterogeneity of the ribonucleic acid in microsomal[11-14] and supernatant[4,8,11,12] fractions. Published procedures[12-18] were not ideal for the purpose of partitioning the ribonucleic acid among several sub-fractions. This purpose has now been achieved by fractionating tissue proteins (ribonucleoproteins ?) under mild conditions as described below, with tissue samples isolated at different times after injection of orotic acid-6-^{14}C; the time course of ribonucleic acid labelling served as a guide in choosing conditions for separation.

Tissue fractions. Liver homogenates, prepared with 0·25 *M* sucrose from fasted rats given labelled orotic acid, were freed from nuclei and mitochondria, and centrifuged for 90 min. at 14,500 *g* to give microsomal and supernatant fractions[3,4]. (The 'ultracentrifugal pellet' which can be obtained by re-centrifugation at a higher *g* value, and which would be included in the 'microsomal' fraction in some laboratories[5,13], resembles our 'ultracentrifugal supernatant' fraction rather than our microsomal fraction in its time course of labelling[4,8] and in its changes after adrenalectomy[2-4] or in liver tumours[1].) The fractions were frozen and stored at − 30°; with microsomal fractions the freezing facilitated the subsequent extraction of ribonucleoprotein.

Analytical methods. Solid samples were counted at infinite thickness, and analysed for ribonucleic acid as previously[3,4]. Almost all the original ribonucleic acid was recovered in the sub-fractions[13,17]. For the subsequent isolation of ribonucleic acid mononucleotides, digestion was performed with 1·5 *N* potassium hydroxide for 42 hr. at 37°, to ensure complete conversion of the ribonucleic acid to mononucleotides[19,20]. The digest was treated with perchloric acid (to 3 per cent) to remove protein, neutralized with potassium hydroxide, centrifuged to remove perchlorate, and applied to a 'Dowex 1' (formate) column. Gradient elution chromatography was carried out with formic acid[21] to give individual nucleotides, with no attempt[20] to separate 2′- and 3′-isomers. The extinction readings (260 mμ) were assumed to be a valid measure of the amounts present, except for cytidylic acid which, being contaminated with protein[20], was estimated by analysis of the peak for phosphorus. A further difficulty with cytidylic acid is that some deamination, to give uridylic acid, may occur during the digestion[20,22]; however, this deamination was probably slight because of the presence of tissue protein[19]. Values are expressed relative to guanylic acid as being probably least open to errors of estimation, and are quoted as 'apparent' base composition, since there may still be undetected errors in the present methods. The radioactivity of nucleotide solutions was determined at infinite thinness, with aliquots dried on duralumin planchets.

Supernatant fraction. All fractionations were carried out at about 2°. The procedure for the supernatant fraction (Fig. 1) was based on previous experiments[4]. The ribonucleic acid precipitated by calcium ions partially redissolved on treatment with oxalate[14]. Both the residual ribonucleic acid and the re-dissolved portion which remained soluble on adding streptomycin sulphate[18] seemed, on the grounds of labelling results, to be worthy of closer examination, together with ribonucleic acid precipitated from the calcium-soluble fraction by ammonium sulphate[4] at 40 per cent of saturation. There appeared to be differences in base composition (Fig. 1), the last-named fraction being deficient in guanine; but attention is directed particularly to the differences in the time course of ribonucleic acid labelling (Fig. 2). The peak of labelling lay at about 12·5 hr. for the ammonium sulphate (40 per cent) precipitate, at about 20 hr. for the streptomycin supernatant and not earlier than 42 hr. for the residual (oxalate-insoluble) ribonucleic acid. (Note logarithmic axes.)

If the ribonucleic acid with a peak at 12·5 hr. were the precursor of that in other sub-fractions, it should have relatively high labelling up to 12·5 hr.[23]. Here it is necessary to consider the labelling not of ribonucleic acid as a whole but of the uracil moiety, since, as has now been confirmed, the labelling of

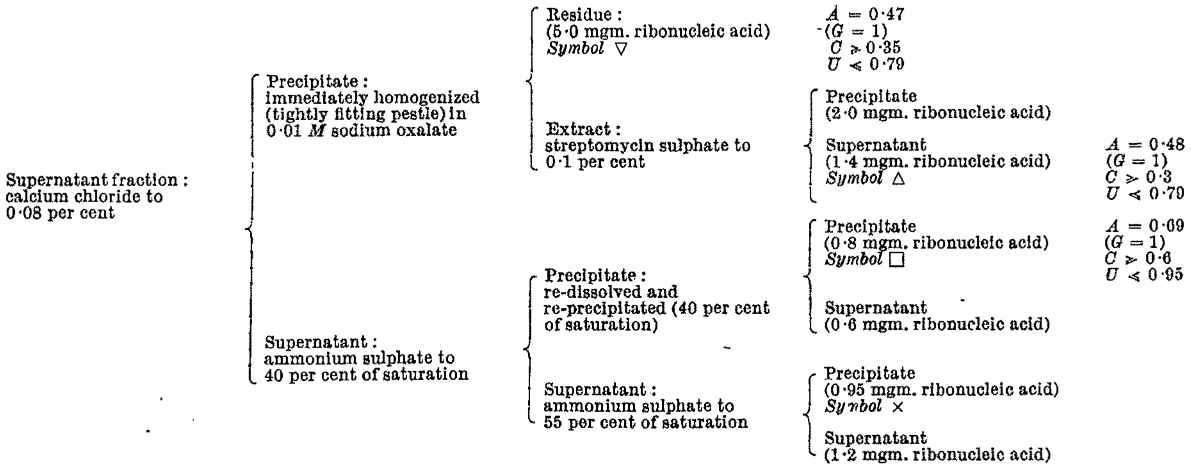

Fig. 1. Sub-fractions from supernatant fraction. In Figs. 1 and 4, the yields of ribonucleic acid refer to an amount of liver corresponding to 100 gm. body weight; the symbols are those used in Figs. 2–6, and *A*, *G*, *C* and *U* denote adenylic, guanylic, cytidylic and uridylic acids, respectively. The mean values for the apparent base composition (see text) are given as molar ratios

cytosine is initially low but eventually as high as that of uracil[6]. Fig. 3 shows that the ribonucleic acid uracil of this sub-fraction does rapidly attain high labelling.

Since it was conceivable that the 'rapidly labelled ribonucleic acid' comes directly from acid-soluble nucleotides, possibly uridine triphosphate or uridine diphosphate[10], these nucleotides were isolated for study[4,6,21]. There was no wide gap[6] between their peak of labelling and the peak for the 'rapidly labelled ribonucleic acid' (Fig. 3). In contrast with uridine triphosphate, the diphosphate had persistently high labelling which greatly exceeded that attained by ribonucleic acid uracil. It should be mentioned that all experiments were made with a single batch of orotic acid (prepared by Dr. V. C. E. Burnop); with a different batch (from the Radiochemical Centre, Amersham) used in another study[1], higher nucleotide and ribonucleic acid labelling has been encountered at short time intervals.

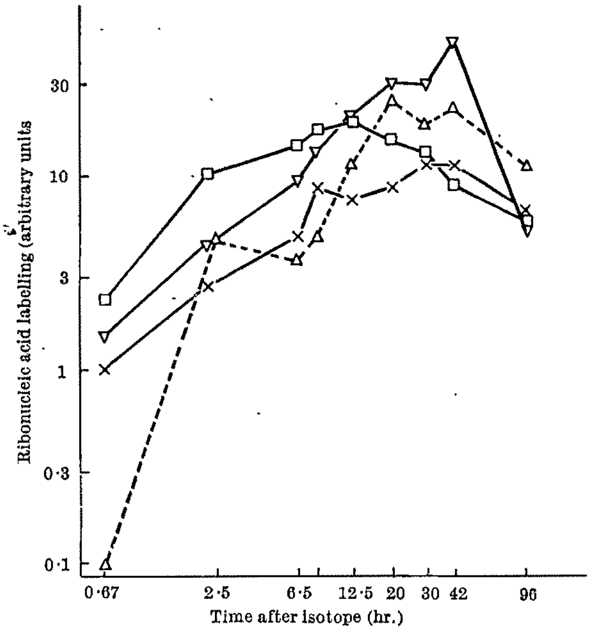

Fig. 2. Labelling of ribonucleic acid in sub-fractions from the supernatant fraction (see Fig. 1 for symbols). The axes in Figs. 2, 3, 5 and 6 are logarithmic, and the values refer to an injection of orotic acid equivalent to 1 μc./100 gm. body weight; each point represents tissue samples from at least two rats. The arbitrary units in which specific radioactivity is expressed in Figs. 2 and 5 are (counts per min.)/(per cent ribonucleic acid in sample counted), with constant sensitivity in the counting

Trial of an alternative fractionation procedure—precipitation at *p*H 5 in the presence or absence of buffer—indicated that the course of labelling of the precipitated ribonucleic acid (which may play a part in amino-acid incorporation[5]) resembled that of the soluble ribonucleic acid. The procedure of Kirby[24] also failed to give sharp separation.

Microsomal fraction. Fig. 4 summarizes the procedures. Ribonucleoprotein particles (Palade particles) from microsomes would probably be essentially intact if present in the *p*H 7·4 buffer or even in the *p*H 9·0 buffer[16]. Since, however, the residue

Fig. 4. Sub-fractions from microsomal fraction. See legend to Fig. 1

from the *p*H 9·0 extraction was still rich in these particles as judged by electron microscopy (kindly performed by Mr. M. S. C. Birbeck), it is conceivable that the ribonucleic acid extracted by buffer is derived not from these particles but from reticular elements[11]. The non-extracted ribonucleic acid was effectively solubilized by treatment with the non-ionic detergent 'Triton X–100'; treatment with phenol[24] was equally effective, but subsequent fractionation procedures[24] gave rather variable results.

Two fractions from the first (*p*H 7·4) extraction were given especial attention—a streptomycin precipitate, and an ammonium sulphate precipitate which had a later peak of labelling (Fig. 5). The ratio of adenine to guanine differed little among these and other sub-fractions examined, but there were apparent differences in the ratio of cytosine to uracil (Fig. 4). The *p*H 5-soluble material from the second (*p*H 9·0) extract showed labelling which was variable but notably low (Fig. 5). The residual ribonucleic acid which was solubilized by the detergent gave, with streptomycin, a precipitate which had an earlier peak of labelling than the supernatant.

Values obtained for uracil (Fig. 6) were essentially in accord with those for the labelling of ribonucleic acid as a whole. Comparison of the curve for the

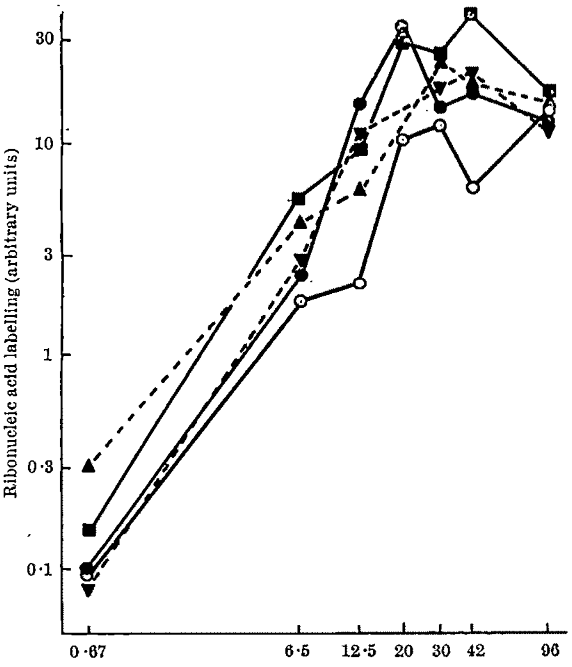

Fig. 5. Labelling of ribonucleic acid in sub-fractions from the microsomal fraction. See Fig. 4 for symbols, and legend to Fig. 2 for units

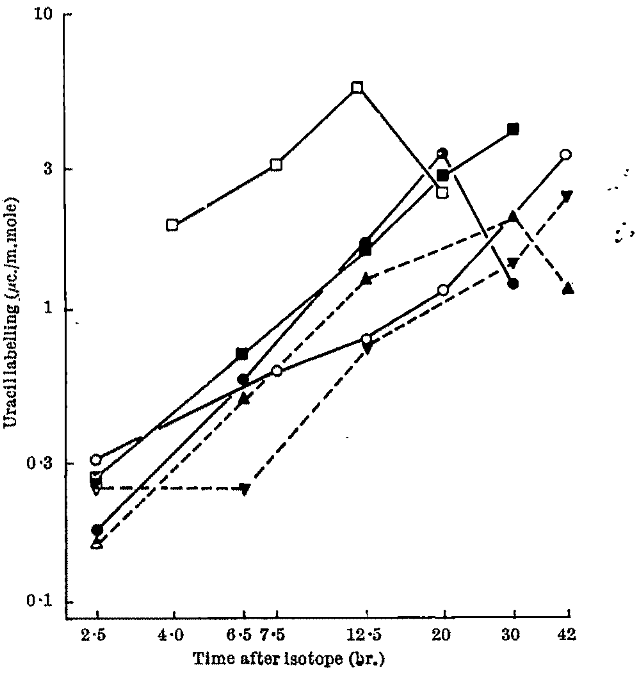

Fig. 6. Labelling of uracil in the ribonucleic acid of sub-fractions from the microsomal fraction (see Fig. 4 for symbols) and in the ribonucleic acid of the 'rapidly labelled sub-fraction' from the supernatant fraction (□; cf. Fig. 3)

microsomal sub-fraction having the earliest peak (at about 20 hr.) with the curve, reproduced from Fig. 3, for the 'rapidly labelled ribonucleic acid' from the supernatant fraction suggests that here there could be an inter-relationship[23].

Conclusions. With rats given labelled orotic acid, differences have been found in time and magnitude of maximum labelling among ribonucleic acid sub-fractions derived from microsomal and supernatant fractions; the results agree with the finding[4] that the supernatant fraction as a whole becomes labelled earlier than the microsomal fraction. The peaks ranged from about 12·5 to more than 42 hr., the earliest being observed with ribonucleic acid separated from the calcium-soluble portion of the supernatant fraction. Qualitatively, the results are not incompatible with the possibility that this 'rapidly labelled ribonucleic acid' is formed directly from acid-soluble nucleotides, and is a precursor, direct or indirect, of other ribonucleic acid constituents of the supernatant and microsomal fractions. There appear to be differences among the sub-fractions in base composition. Speculation on possible chemical transformations undergone by the 'rapidly labelled ribonucleic acid' must await further study, especially as to the homogeneity and molecular size of the various ribonucleic acid constituents. The microsomal sub-fractions warrant study with respect to amino-acid incorporation into protein, but this incorporation may well be uncorrelated with ribonucleic acid labelling[13,14].

Acknowledgments. Facilities for the isotopic experiments were kindly provided by Prof. J. A. V. Butler, Dr. L. F. Lamerton and Dr. N. G. Trott. Thanks are expressed to Mr. J. T. Nodes and Mr. R. T. Charles for certain assistance, and to Dr. A. L. Greenbaum for comments on the manuscript. Support was given by a Gordon Jacobs Fellowship (B. M. S.) and by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

AGE DETERMINATION FOR INDIVIDUAL *MANSONIOIDES* MOSQUITOES

By Prof. D. S. LERTRAM and W. A. SAMARAWICKREMA

Department of Entomology, London School of Hygiene and Tropical
Medicine, Keppel Street, London, W.C.1

The age of the individual insect living entirely naturally has long challenged the interest and ingenuity of entomologists in many fields. For medically important insects, one of many factors in the epidemiology of the diseases they carry is the proportion of a population of a vector species living long enough to transmit pathogens which undergo, before transmission can take place, cyclical development within the insect for some days or weeks. Means of telling the age of mosquitoes—vectors of malaria, filariases and virus infections involving extrinsic cycles of this nature—have been sought from time to time by numerous workers, notably for anopheline carriers of malaria.

The most promising and useful methods still depend on changes in the internal reproductive organs of the female mosquito during its gonotrophic cycles. In each cycle it matures and eventually lays its eggs in the few days following a blood meal; there may be several gonotrophic cycles, each lasting two or more days, in the life-time of a mosquito. Mer[1] showed first for *Anopheles elutus* that the ampulla, a dilatation of the oviducts, increased in diameter with the first oviposition to a degree which served to differentiate recently emerged females which had not laid eggs from older individuals which had laid one or more batches. Later workers confirmed this method for distinguishing nulliparous from older, parous females in some other anopheline species; Davidson[2] elaborated the principle on a statistical basis to derive a daily survival-rate for *A. gambiae*. New departures were made by Gillies in the recognition of young females (pre-gravids) of this species on the basis of partial ovarian development only after their first blood meal[3], and by the presence of a mating plug in the common oviduct[4]. The undoubted value, and also limitations of these, and certain other methods, for determining the longevity of mosquitoes are indicated by Macdonald[5] in his analysis of factors in the epidemiology of malaria. It may be emphasized here that none of these methods is suitable for telling the actual age of the individual mosquitoes making up the older, parous group. This leaves much to be desired. Thus, in favourable climatic conditions nullipars are generally no more than about two or three days old; parous females may be only a day or so older or have lived nearly as long as, or longer than, the extrinsic period of the parasites they may happen to harbour, usually a period of 10–14 days. The last may be actively transmitting the disease, the others may yet survive to do so. In mosquito control work, it would be invaluable to be able to determine with considerable accuracy the age of any individual mosquito caught in the control area. This would be particularly convenient in the early detection of individuals resistant to insecticide in a surviving mosquito population of very low density. It would also be relevant to checking the efficacy of control in the earlier phases of an eradication scheme or where, for various reasons, it may only be practicable to prevent transmission by reducing mosquito longevity to less than the extrinsic period of the pathogen. Apart from practical issues of this kind, accurate age determination of individual mosquitoes would be of immense interest in purely biological studies on their behaviour.

Recently, there have been notable developments towards a solution to this problem. Russian workers, in fact, made important progress in this direction nearly a decade ago. Several months ago, Dr. M. T. Gillies prepared translations of papers published by Polovodova[6] and Detinova[7] in 1949, advance copies of which he kindly made available to us, and others. The Russian work showed for *Anopheles maculipennis* that when an egg passes from its follicle at oviposition it leaves behind a corpus luteum in the form of a dilatation of the tube connecting the ovariole to the lumen of the oviduct in the ovary. This persists through subsequent gonotrophic cycles, each of which in turn is marked by a residual corpus luteum. Thus, the number of these corpora lutea in an ovariole indicates the number of gonotrophic cycles completed by the mosquito. If the duration of a cycle is known, it is then possible to tell the age of the individual mosquito with considerable precision. Some ovarioles do not produce an egg in every cycle, so that the maximum number of corpora lutea per ovariole must be noted. A fuller account of the Russian work has been prepared by Gillies[8]. Recent independent studies by Colless[9] on certain Malayan culicines seem to demonstrate the same criterion for age determination in three species of *Culex* and in *Aedes albopictus*. Lewis[10] reports some preliminary observations on the ovarioles of *A. gambiae* but does not develop the subject beyond the recognition of nulliparous from parous females.

Species of *Mansonioides* are among the mosquitoes of medical importance, primarily as vectors of filariasis of man in the Oriental region, but with some implications also as possible vectors of yellow fever and other viruses. They can be a severe biting nuisance. Their role as vectors of parasites and disease to animals, and possibly man, may well be shown in future to be greater than is generally accepted at present. Colonies of several species of *Mansonioides* have been maintained in our laboratory for about three years using the methods of Laurence and Smith[11]. It was convenient and of interest, therefore, to examine the possibility of determining the age of individual *Mansonioides* females by a count of their corpora lutea, as described for *A. maculipennis* and suggested for *Culex* and *Aedes*. This article reports that in the *Mansonioides* mosquito a corpus luteum remains to mark each gonotrophic cycle and that the maximum number of corpora lutea found in the ovarioles of its ovaries is a valuable index to the actual age of the mosquito.

The experiments demonstrating this were, briefly, as follows: adult mosquitoes were kept in 25 cm. cube cages of wood frame and plastic netting at 26–30° C., humidity within the cages being maintained by damp lint on top of the cages, which were also draped with a thin polyethylene case. Except when being starved before a blood meal, the adults had access in their cages to cut apple and to sugar solution in cotton-wool. Females were fed on blood by inserting the human hand inside a cage. They first fed readily three days after emergence. Gorged females were transferred to a separate cage, as described, and became gravid four days later. When removed to large beakers containing water and floating *Salvinia*, they oviposited on the plant almost at once. In these experiments, a second blood meal was given within 12–18 hr. of oviposition. The second gonotrophic cycle was completed in four days. This procedure was continued with *Mansonioides uniformis* and *M. annulifera* through, respectively, six and three cycles, and representative females were dissected at suitable intervals for ovariole structure. The ovaries were dissected out in 0·9 per cent saline. Ovarioles were then released by breaking the membrane investing the ovary with a fine needle and teasing the tracheal supply aside carefully. With some practice, the corpora lutea could be exposed with considerable ease and counted under a stereoscopic microscope magnifying at × 30.

Results are given in Table 1, and illustrated in Figs. 1 and 2. Fig. 1 shows the germinal area, first follicle and simple pedicel in the ovariole of a three-

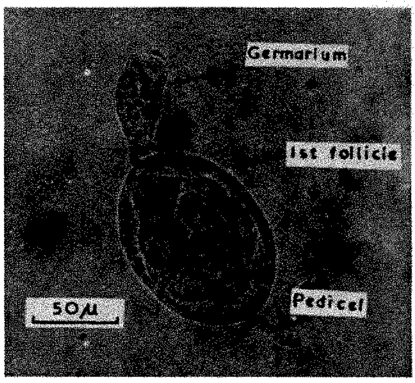

Fig. 1. Ovariole of 3-day old nulliparous *M. uniformis*

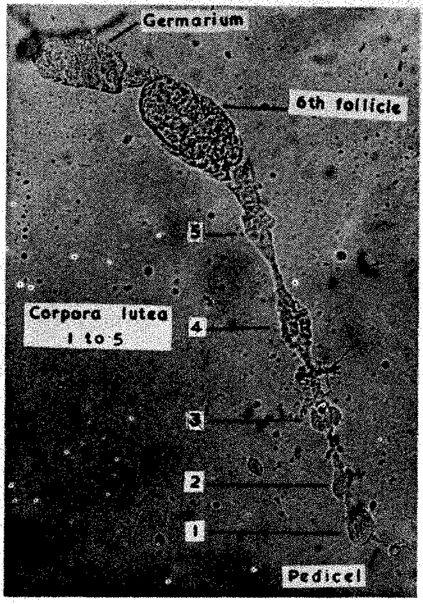

Fig. 2. Ovariole of 23–24-day old parous *M. uniformis*, after five gonotrophic cycles. (Magnification as Fig. 1)

day-old, unfed *M. uniformis* female. Fig. 2 is an ovariole isolated from the ovary of a 23–24-day-old female of *M. uniformis* after five blood meals and ovipositions had been completed. The five corpora lutea each represent a gonotrophic cycle lasting about four days and the first blood meal was given when the mosquito was three days old. Agreement is very close indeed between the actual known age of this individual and the calculated age, based on the number of corpora lutea found and the time required for each gonotrophic cycle. Other individuals killed earlier in the series and with fewer gonotrophic cycles completed showed corresponding maximum numbers of corpora lutea in the ovarioles. Similar results were obtained with *M. annulifera*. These results demonstrate for *Mansonioides* findings similar to those reported for *A. maculipennis*, *Culex* spp. and *Aedes albopictus*. This method of telling the age of any individual mosquito seems, therefore, likely to be widely applicable in mosquitoes generally. It promises to be of great value in elucidating problems in mosquito behaviour, either natural or under pressure of control.

Table 1. Showing, for *M. uniformis*, the Maximum Number of Corpora Lutea in an Ovariole in Relation to the Experimentally Known Age and Physiological State of the Mosquitoes

	Maximum number of corpora lutea in an ovariole	Age of females in days
Emerged and unfed	0	3
After first oviposition	1	7–8
After second oviposition	2	11–12
After third oviposition	3	15–16
After fourth oviposition	4	19–20
After fifth oviposition	5	23–24
After sixth oviposition	6	27–28

INDUCTION OF RESPIRATORY DEFICIENCY IN YEAST BY MANGANESE, COPPER, COBALT AND NICKEL

By Prof. CARL C. LINDEGREN, SUSUMU NAGAI and HIDEKO NAGAI

Biological Research Laboratory, Southern Illinois University, Carbondale, Illinois

AMONG the chemical agents which induce respiratory deficiency in yeasts, acriflavine[1], triphenyl tetrazolium chloride[2], *p*-nitrophenol[3], and propamidine isethionate[4] are especially effective in producing the deficiency in a large fraction of the surviving population. The present work is a survey of the efficacy of various metallic salts in inducing respiratory deficiency.

Respiratory-sufficient yeasts containing fewer than 1 per cent respiratory-deficient cells when grown under normal conditions were chosen from the Lindegren breeding stocks. Efficacy in inducing respiratory deficiency (during growth) was tested by growth in the following nutrient medium (to which the various agents to be tested were added later): magnesium sulphate ($MgSO_4.7H_2O$), 0·5 gm.; potassium dihydrogen phosphate, 1 gm.; ammonium sulphate, 1·5 gm.; 'Bacto' peptone, 1·8 gm.; 'Bacto' yeast extract, 2 gm.; glucose, 10 gm.; U.S.P. agar, 20 gm. dissolved in 1,000 ml. of water. Concentrated stock solutions of the various agents (usually 2·5 per cent) were sterilized separately and added to the medium at temperatures around 50° C.

Respiratory deficiency was scored by the triphenyl tetrazolium chloride-overlay method[5]. (1 mgm./ml. of triphenyl tetrazolium chloride was dissolved in molten 1·5 per cent 'Bacto' agar adjusted to *p*H 7·0 with *M*/15 phosphate mixture, cooled to 50° C., gently poured over the diagnostic plate cultures and incubated at 30° C. Respiratory-sufficient colonies turn dark red within an hour while respiration-deficient colonies remain white.) Medium for the

MACMILLAN BOOKS

The Economics of International Migration

EDITED BY *BRINLEY THOMAS*

Trends in international migration have been profoundly changed in the last thirty years by the American Restriction Act of 1924, the great depression of the early 1930's and the Second World War. Twenty-four papers on the subject by leading experts, and a record of the discussions of the seventh conference of the International Economic Association. 45*s*

Textbook of Economic Analysis

EDWARD NEVIN, M.A., PH.D.

An introduction to the groundwork of contemporary economic and monetary theory. Assuming no previous knowledge on the part of the reader, it sets out to explain the nature and scope of economic analysis, and then proceeds to an exposition of the modern theories of demand, supply, value and income distribution. Finally, the book deals with the issues arising from international transactions. 'With this book Dr. Nevin will earn the gratitude of many teachers, to say nothing of their students. It undoubtedly fills a gap in first-year reading lists.'—*Accountancy.*

With diagrams 18*s*

An Atlas of Airborne Pollen Grains

H. A. HYDE and K. F. ADAMS

This atlas is intended primarily as an aid to the identification of pollen grains in the fresh condition. The ninety-two species described are those which can be observed at a magnification of about 1,000 diameters. The book should be of value in studies of airborne pollen in general and in relation to hayfever, and, to a lesser degree, the pollen loads of bees, and pollen in honey and in peat. *Illustrated* 36*s*

General Microbiology

ROGER Y. STANIER, MICHAEL DOUDOROFF and EDWARD A. ADELBERG

This book attempts to present a modern synthesis of microbiological knowledge for university students of the biological sciences. Students new to this subject will find it particularly useful. *With photographs and diagrams* 50*s*

St Martin's Street London WC2

Only very occasionally does a new material appear that has a widespread potential throughout industry.

Here, though, is just such a product — a unique material that deserves your fullest understanding.

Refrasil

is the name given to a lightweight fibrous silica material, of very fine diameter, which is capable of withstanding continuously temperatures in the order of 1,000°C, or for short periods, even above. It has outstanding thermal insulating characteristics at elevated temperatures, as well as being an excellent high temperature electrical insulator. Like fused silica it has a high resistance to thermal shock and to chemical attack from acids.
It is available as batt, felted wool, cloth, tape, sleeving, bulk fibre, cord, and yarn.
There are many other things well worth your knowing about Refrasil; we have incorporated them all in a brochure which we would like to send you.

REFRASIL

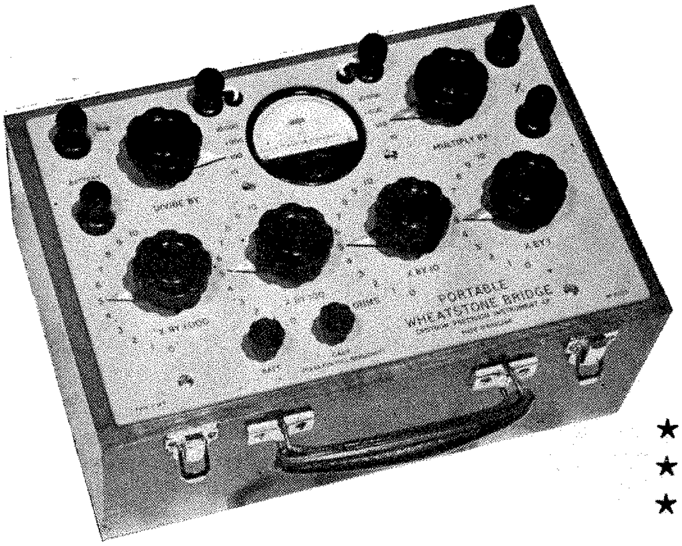
PORTABLE WHEATSTONE BRIDGE

Type P.W.2.



A robust, compact, portable instrument for workshop, field or educational use.

It is complete with supply batteries and sensitive pointer galvanometer.

The overall range is 0.001 ohm to 10 megohms and the practical measuring range is 0.01 ohm to 1 megohm.

Provision is made for using the bridge with an external galvanometer and the variable arm of the bridge can be used as a resistance box.

It is fitted with a lid and carrying handle.

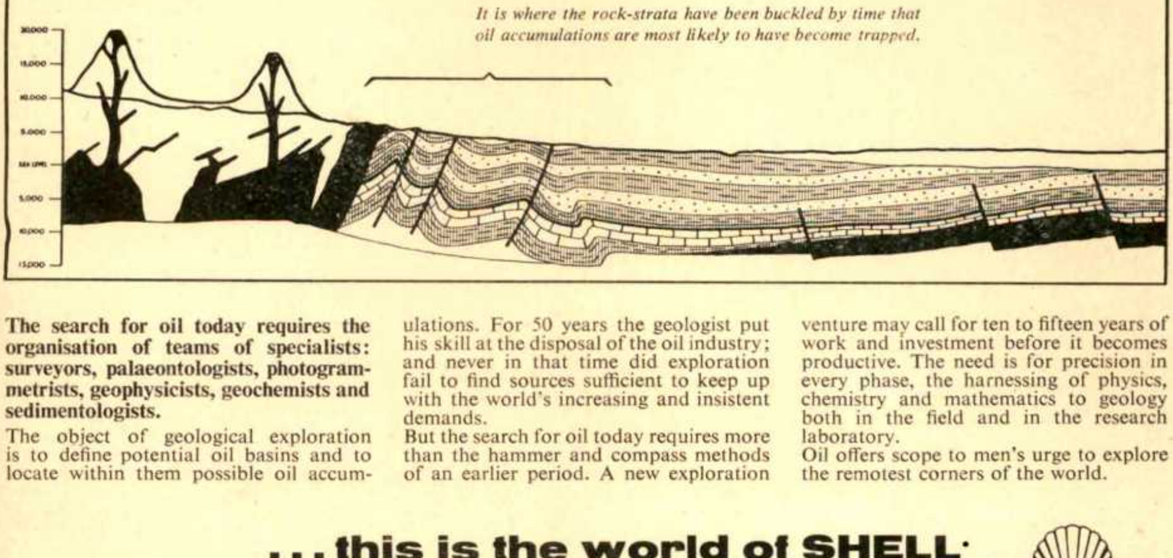
REPRESENTATION OF GEOLOGICAL SECTION ACROSS THE ANDES OIL BASIN



It is where the rock-strata have been buckled by time that oil accumulations are most likely to have become trapped.

The search for oil today requires the organisation of teams of specialists: surveyors, palaeontologists, photogrammetrists, geophysicists, geochemists and sedimentologists.

The object of geological exploration is to define potential oil basins and to locate within them possible oil accumulations. For 50 years the geologist put his skill at the disposal of the oil industry; and never in that time did exploration fail to find sources sufficient to keep up with the world's increasing and insistent demands.

But the search for oil today requires more than the hammer and compass methods of an earlier period. A new exploration venture may call for ten to fifteen years of work and investment before it becomes productive. The need is for precision in every phase, the harnessing of physics, chemistry and mathematics to geology both in the field and in the research laboratory.

Oil offers scope to men's urge to explore the remotest corners of the world.

First Quality

STOP WATCHES

for Scientific use

This 01 stop watch is ideal for general laboratory use. It combines a 1/5th second escapement with a 30 minute recorder. In the same series is model 03 with a 1/10th second escapement and a 15 minute recorder. Both watches are characterized by their high accuracy and relatively low cost.

Repair service. Our skilled repair staff deals with all types of watches, clocks and associated equipment. "Crash" service—ring MUSeum 2255.

Sectional catalogues and leaflets available

Watches, stop watches and chronographs. Clocks: aircraft, domestic, industrial, architectural and turret. Revolution counters, tachographs and associated equipment. Process timers and time interval meters. Electronic instruments.

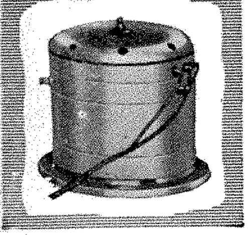
Vibrators ***for fatigue testing***

Guided missiles, aircraft and all forms of industrial components . . .



★ *Our Technical Dept. is always available to give assistance on any Vibration problems.*

TYPE V1001. This vibrator is of the moving coil type with a wound field magnet energised from an external source of direct current. It is continuously rated and therefore suitable for extended fatigue testing as well as for intermittent use in research, development and production work.

The useful frequency range is up to 5 kc/s.

The design of the vibrator is such that the electrical impedance of the "speech coil" shows only a slight rise at the higher frequencies and this obviates the need for frequent output transformer tap changing as the frequency is varied.

SPECIFICATION

Height .... 20 in.
Dia. of base .... 35 in.
Fixing holes, No. and size as required on 33¼ in. P.C.D.
Weight......1 ton 15 cwt. 10 lb.
Table..................... 18 in. dia.
Thrust...............3,000 lb. pic.
Excursion......... 0·500 in. max.
Max. permitted acceleration 100 "G"
Direct current force factor 36 lb./amp.
Max. input...... 64 amps (r.m.s.)
Moving coil blocked impedance 1·5 ohms (est.)
D.C. resistance of moving coil 0·875 ohms
Field coil current......4·6 amps.

diagnostic plates was double-strength, except for glucose and agar, as compared with the medium containing the various agents. (The medium on the diagnostic plates was that ordinarily used in this laboratory, while the medium containing the salts was half-strength except for agar and glucose. Preliminary experiments had revealed that 'diluted' medium produced more deficient variants than full-strength medium.)

Treatments in liquid media were carried out in 20 ml. of medium in 50-ml. Erlenmeyer flasks, or 40 ml. of medium in 200-ml. flasks. Cells were sampled for inoculation on the diagnostic plates, usually after incubation for about 24 or 48 hr. at 30° C. Ammonium sulphate, peptone and yeast extract were omitted from some media, which were designated 'nitrogen-starvation' media.

Rapid surveys were achieved with gradient agar plates[6] containing the agent to be tested in the upper layer. Heavy suspensions of 1-day-old cultures were streaked on gradient plates and incubated for 48 hr. The streaks faded out gradually (instead of ending abruptly) after the range of confluent growth. In seeking to determine the effects produced on the Szybalski plates, cells were sampled from the intermediate region and spread on diagnostic plates after adequate dilutions.

Three strains, 14061 (haploid), *F*-2 (diploid) and 11294 × 11296 (tetraploid), were inoculated in liquid media supplemented with various concentrations of manganous sulphate and allowed to proliferate. When samples were diagnosed for respiration deficiency, red (sufficient), white (deficient) and sectored or variegated colonies appeared. The sectored colonies were red colonies with usually three or more white sectors; the variegated colonies had a dark red centre and white periphery, suggesting delayed response in the change from respiratory sufficiency to deficiency. Concentrations below 0·12 per cent were ineffective in inducing respiratory deficiency (Table 1). Nitrogen-starvation medium yielded very few deficiencies.

Manganous chloride was found to produce the same effect as manganous sulphate.

Manganous sulphate is only slightly toxic to yeasts. The survivors of the tetraploid culture (11294 × 11296) (spread on plates containing 0·17 and 0·33 per cent manganous sulphate) were 85 and 48 per cent, respectively. Colonies grown on manganese agar suspended in water and spread on diagnostic plates were found to contain approximately the same percentages of respiratory-deficient cells as similar cultures grown in liquid media containing manganese.

To test the possibility that respiratory-deficient cells may have a competitive advantage over respiratory-sufficient cells in medium containing manganous salts, cells were picked up by a micromanipulator from a 1-day-old tetraploid (11294 × 11296) culture in standard medium and transferred separately to standard and 0·17 per cent manganous sulphate agar and allowed to proliferate for 72 hr. Of twenty cells transferred to manganous sulphate agar, thirteen formed colonies. Samples from suspensions of those colonies contained 45–65 per cent respiratory-deficient cells. Eighteen colonies formed on normal agar (two out of twenty failed to grow) contained less than 1 per cent respiratory-deficient cells. It may be inferred that each colony started from a single respiratory-sufficient cell and produced respiratory-deficient cells at high frequencies during proliferation in the presence of manganous sulphate. The frequent occurrence of sectored and variegated colonies (which generally decrease with time) also supports the view that induction has occurred.

Growth of the respiratory-sufficient diploid (*F*–2) culture was followed in 50-ml. flasks in the presence and absence of manganous sulphate. A respiratory-

deficient culture derived from the same strain (by treatment with manganese) was tested in parallel. The respiratory-sufficient culture grew slightly better than the respiratory-deficient one in the absence of manganese. The respiratory-sufficient culture in the presence of manganese produced many deficient cells, but a large fraction of respiratory-sufficient cells persisted indicating that respiratory-deficient cells do not have an overwhelming relative advantage. The respiratory-deficient culture was slightly inhibited in the presence of manganese.

Cupric sulphate ($CuSO_4.5H_2O$), cobaltous chloride ($CoCl_2.6H_2O$) and nickelous chloride ($NiCl_2.6H_2O$) are more toxic than manganous salts, but sublethal concentrations led to the production of the respiratory-deficient cells (Table 2). The cultures differ markedly in sensitivity to copper, and the results suggest that more respiratory-deficient variants are produced by resistant cultures than by sensitive ones.

Sodium chloride, potassium chloride, lithium chloride and strontium nitrate are much less toxic than copper, cobalt and nickel. Growth of haploid culture 14061 and tetraploid 11294 × 11296 was suppressed by 5·8 per cent sodium chloride, 7·4 per cent potassium chloride and 0·25 per cent lithium chloride. Strontium nitrate up to 0·6 per cent did not inhibit growth (higher concentrations could not be tested because of the formation of a precipitate). Even at concentrations which suppressed growth most of the inoculum survived after two days. Samples from treated flask cultures did not show any increase (over controls) in the frequency of the respiratory-deficient cells.

The inhibitory concentrations of mercuric chloride, potassium dichromate and arsenic acid were, respectively, 0·005 per cent, 0·01 per cent, 0·05 per cent. No increase in the frequency of the respiratory-deficient cells (above controls) was detected either in liquid medium or on gradient plates. This may be because the high toxicity did not permit sufficient growth for the expression of the phenomenon. Cultures grown in the presence of arsenic acid produced many dwarf colonies but were all red under the triphenyl tetrazolium chloride-overlay.

Respiratory deficiency in yeast may be the result either of destruction or inactivation of a cytoplasmic granule or mutation of a gene. Ephrussi[1], Laskowski[2] and Yanagishima[3] have shown that this condition may be induced with high frequency during growth by different organic poisons. The inorganic ions manganese, copper, cobalt and nickel induce respiratory deficiency in yeasts with high frequency. The high frequency of induction and the relative independence of ploidy suggests that most of the respiratory deficiencies induced by these ions are due to the destruction or inactivation of cytoplasmic granules rather than to effects on the genome. The alkaline earths, sodium, potassium, lithium and strontium, seem incapable of inducing respiratory deficiency. Mercury and arsenic failed to reveal any increase in respiratory deficiency above controls, but this may be due to their extreme toxicity.

Manganous salts were very slightly toxic, but induced respiratory deficiency with great efficacy. Demerec[7] classified manganous salts as 'very mutagenic' because of their mutagenic (?) effect on *Escherichia coli*, but the effect of manganous salts on yeasts seems to be due almost exclusively to their effect on cytoplasmic granules rather than on the genome.

It is commonly said that most mutagens (meaning agents which cause gene mutation) are carcinogens, and it has been inferred that the problem of cancer is related in some way to the structure of the deoxyribonucleic acid. This inference rests on the assumption that gene mutation is an important factor in carcinogenesis. Many of the effects, however, which are ascribed to gene mutation may be due to the damage to the autonomous cytoplasmic granules, and such carcinogens as ultra-violet and X-rays have often been demonstrated to produce stable variations in the extra-chromosomal apparatus. Re-evaluation of ideas relating gene mutation to carcinogenesis may be in order.

This work was supported by the Illinois Division of the American Cancer Society.

Note added in proof. Caffeine at concentrations of 0·2 per cent was similarly found to be highly efficacious in the production of respiratory deficiency.

DIRECT OBSERVATION OF DISLOCATIONS IN GRAPHITE

By Dr. ALEXANDER GRENALL

Atomics International, North American Aviation, Inc., Canoga Park, California

RECENT electron microscopy work has revealed the presence of dislocations in graphite. The nature of these dislocations and their movement within the structure of the crystals have been studied and recorded by means of motion pictures. Many of the features of dislocation arrangement and motion described by Hirsch, Horne, Whelan and Bollman for aluminium[1] and stainless steel[2] have been observed also in the case of graphite. Single dislocations occur within crystal grains, line up to form sub-grain boundaries, form dislocation networks (square and hexagonal cross-grids), and are spontaneously generated at crystal edges. Examples of sub-grain boundaries (small-angle misfit boundaries) formed from aligned single dislocations are shown at *A* and *B* in Figs. 2*a* and 2*b*. An example of cross-grid dislocation networks is exhibited in Fig. 1*a*. These photographs and the others to be discussed were taken from the motion picture sequences and have not been retouched.

Sub-grain boundaries and cross-grids have been observed to undergo modification under thermal stress. They move about and undergo rearrangement and in some cases disappear completely after a time. The pinning of sub-grain boundaries by an obstacle in the graphite structure has been observed and photographed. As the obstacle was encountered, the motion of a section of the aligned dislocations making up the sub-grain boundary was slowed and brought almost to a complete halt. This resulted in a bowing of the sub-grain boundary. The nature of the obstacle was not determined.

To illustrate the above description, comparison of Figs. 1*a* and 1*b*, which are taken from the same motion picture scene but over an interval of time, demonstrates the alteration and almost complete disappearance of the cross-grid dislocation network. Next, study of Figs. 2*a*, *b* and *c* shows how sub-grain boundary *A* moves across the crystal from its position at the left in Fig. 2*a* to an intermediate position in Fig. 2*b*, and finally in Fig. 2*c* occupies the place originally devoted to the dislocation array *B*. This sequence of pictures also demonstrates the pinning and bowing of dislocations around an obstacle. The dislocation array *B* is seen in Fig. 2*a* to have been pinned at point *C* by some unidentified obstacle, and bowing has occurred. In Fig. 2*b* the bowed section of *B* is seen to have passed the pinning point and broken up into individual dislocations, which travel at right angles to the original direction of motion. The final picture of the sequence, Fig. 2*c*, shows that

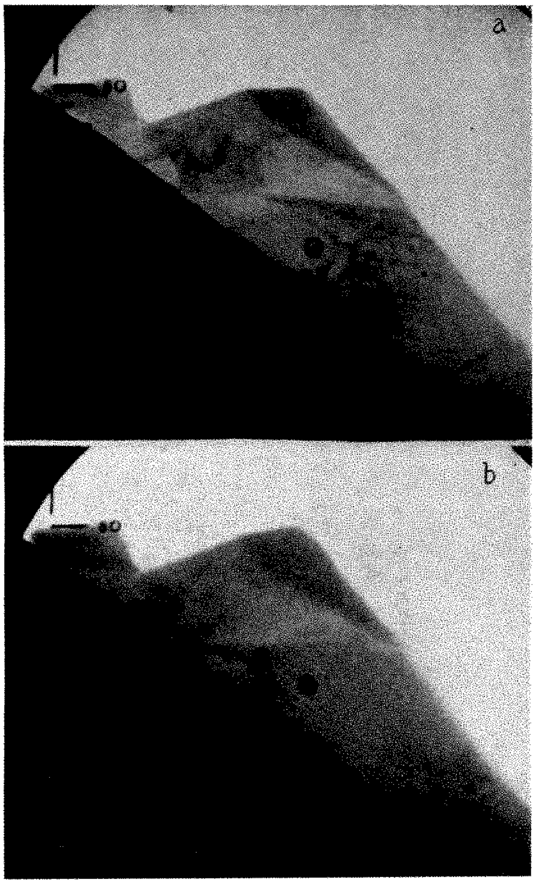

Fig. 1. Sequence of photographs taken from the motion picture film showing the alteration and almost complete disappearance of a hexagonal cross-grid dislocation network. (*a*) The network in early time under the microscope; (*b*) the same field at a later time. (Magnification of all illustrations is × 12,500; the distance between the black line markers is one micron)

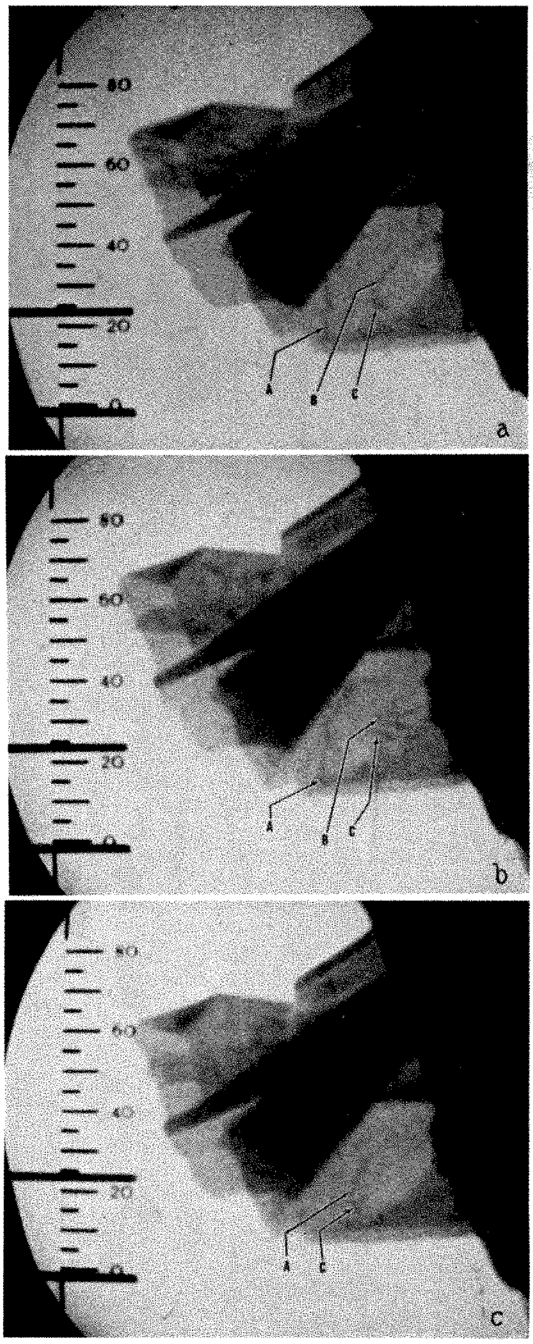

Fig. 2. A sequence taken directly from the motion pictures showing movement of aligned single dislocations forming the sub-grain boundary at *A* in (*a*) to an intermediate position in (*b*), to occupy finally the space originally devoted to dislocation array *B* in (*c*)

This sequence of photographs also demonstrates a pinning point at *C*. In (*a*), array *B* is pinned and bowed around an obstacle at *C*, while in (*b*) the bowed section has passed the pinning point by breaking up into individual dislocations, which travel at right angles to the original direction of motion; (*c*) shows that dislocation array *B* has disappeared by moving out of the crystal and array *A* has moved into this area, has encountered the same obstacle at *C* as array *B* did originally and, as a result, has begun to bow dislocation array *B* has disappeared by moving out of the crystal and dislocation array *A* has moved into this area, has encountered the same obstacle at *C* as array *B* did originally and as a result has begun to bow.

Dislocation motion can be classified as fast or slow. The fast motions consist of a rapid jerky motion, while the slow motions involve a more gradual drifting of the dislocations across a crystal grain. Under the electron microscope, the speed of motion of the black lines indicating the presence of dislocations appears to differ depending upon whether the area of strain is associated with a single dislocation or a network of dislocations. In addition, the speed of motion presumably is determined by whether glide or climb occurs. It appears that glide is characterized by rapid motion while climb results in a slow drifting motion.

Only a brief description of the techniques and findings is given here because it is intended to present these fully in a later publication. The observations were made at 80 kV. in a Norelco *EM* 100*B* electron microscope. The driving force for producing dislocation motion was supplied by the thermal stresses set up by the electron beam. Sample preparation was simple. Natural graphite crystals were placed between two glass microscope slides and sheared by sliding one plate over the other. This action was sufficient to produce small fragments of cold-worked material. These fragments were mounted on a 200-mesh copper specimen screen by rubbing the particles into the screen. The crystals lie on the basal plane, normal or nearly so to the direction of the electron beam. Here and there are thin sections permitting ready observation by transmission of the dislocations as well as other features of the graphite structure. The motion pictures were taken by photographing the fluorescent screen of the electron microscope, operated at 12,500 and 25,000 magnification, by means of a 16-mm. Bell and Howell 70*J* camera, Angénieux *f*/0·95 lens of 1 in. focal length using Tri-*X* film at 16 frames per sec.

FURTHER INHERENT CHARACTERS OF PLANT SPECIES OF WETTER AND DRIER HABITATS

By Dr. M. L. R. PETTERSSON and G. E. J. GRAY
Brunel College of Technology, London, W.3

NOT many centuries after the introduction of alphabetic script, Theophrastus[1] employed this handy medium to record how some species of plant were characteristically found in one kind of community and habitat and some in another. From anthropological evidence, we may presume that this kind of knowledge existed, and was used, by our food-gathering forebears, before even the inception of agriculture. The systematists of the nineteenth century, and the ecologists among others of the twentieth[2], have emphasized the point with a wealth of necessary and erudite observations. But in future years the question will progressively be asked, not where does a species grow, but why does it grow there ; the question of what inherent characters of the plant suit it to such and such an environment[3–6].

The answer must be in terms of comparative anatomy and comparative physiology, including the physiology of growth and development, as describing that genotypic variation among different species upon which ecological selection acts. The comparative ecological anatomy of the first half of the twentieth century[3,5] gives us important clues. But it is now realized that the differences seen in the transverse stem sections of, say, *Ranunculus acris* and *R. aquatilis*, each grown in their natural habitats, may contain large and unassessed components due to induced modification, and that the nature and magnitude of the inherent genotypic difference has, in most such cases, never yet been experimentally determined[7]. The same applies to many earlier observations in comparative physiology[3]. Fresh and more critical comparisons are required between individuals of ecologically contrasting species which have been reared in the same environment.

A useful method of reducing random variation, in such comparisons, is to compare a pair of species which are similar in general structure as well as in seasonal behaviour, such as two species of the same genus[7]. A recent communication[8] describes such an investigation of pairs of species in six genera. In each case, individual plants of an ecologically wetter-living species were reared together with plants of a related drier-living species in a common environment. So far, the behaviour of only one character has been reported ; but it is the present purpose to give a very condensed summary of the behaviour of twenty characters. It is expected that this type of investigation may soon become commoner, since it is both of fundamental importance and of agricultural utility. The pairs of species compared are given in Table 1.

Table 1. PAIRS OF ECOLOGICALLY CONTRASTED BRITISH SPECIES, WHICH ARE COMPARED AFTER BEING REARED IN A COMMON ENVIRONMENT

Genus	Wetter-living species *W*	Drier-living species *D*
Ranunculus	*R. flammula*	*R. bulbosus*
Hypericum	*H. tetrapterum*	*H. perforatum*
Primula	*P. vulgaris*	*P. veris*
Veronica	*V. beccabunga*	*V. chamaedrys*
Centaurea	*C. scabiosa*	*C. nemoralis*
Poa	*P. fluitans* = *Glyceria fluitans*	*P. annua*

Rather than list all the 240 numerical values, only the direction of the deviation need be given, as in Table 2. Taking in each case the value for the drier-living species as a basis, a plus sign indicates that the wetter-living species is found to have a higher value for the particular character ; a minus sign, that the wetter-living species has a lower value ; and a nought, that no difference is reported. Thus the signs are those of (W–D).

Table 2. INTRAGENERIC COMPARISONS, FOR TWENTY CHARACTERS, WITHIN PAIRS OF SPECIES IN SIX GENERA

A plus sign indicates that the wetter-living species of the pair has the higher numerical value for the character concerned. The differences considered are inherent genotypic differences, induced modification having been neutralized (ref. 9)

For a large number of inherent characters, as is of course to be expected, there is no consistent association reported between magnitude of character and humidity of natural habitat. These characters are clearly not, as such, strongly selected by ecological wetness and dryness. This group includes the characters *a*, *b*, *g*, *h*, *i*, *j*, *m* and *o* of Table 2. But these serve as a foil to those other characters, the magnitude of which is more critical for success in wetter or drier environments.

A second group of characters may be distinguished, where there is a preponderant but not invariable relationship. Thus, the wetter-living species of a pair usually, though not always, differs inherently by having: (*c*) less dry weight of lamina; (*d*) greater thickness of lamina; (*e*) a lower degree of development of transpiring surface; (*k*) a higher ratio of lamina fresh weight to cell chromosome number; (*l*) a higher ratio of lamina water content to cell chromosome number; (*n*) a higher ratio of lamina thickness to cube root of cell chromosome number; besides (*p*) a smaller total number of chromosomes in the lamina, as obtained by multiplying the estimate of number of lamina cells by the number of chromosomes in each cell; (*f*) often a smaller number of cells per lamina. With regard to (*e*), this result is in opposition to the views of Huber[11,3]; but his generalization does, of course, apply to the distinction between night-feeding succulent xerophytes and non-succulent mesophytes.

With a third group of characters (sections 4 and 5), the deviations are here found to be invariably in the same direction, which seems to reflect rigorous direct or indirect selection of these inherent characters by ecological wetness or dryness. Thus, in the six genera concerned, the wetter-living species has inherently: (*q*) greater dilation of the lamina and its constituent cells; while its palisade cells, which with regard to size are interspecifically proportional to the average leaf cells[12], have (*r*) greater cell volume per chromosome; (*s*) greater cell water content per chromosome; (*t*) greater cell dry weight per chromosome.

While Maximov[3] did give some experimental evidence that non-succulent species of drier places usually have an inherently higher vacuolar osmotic pressure[13], he did not, in our opinion, prove that they had inherently smaller cells—as he considered he had done[14]—since his chain of argument contains the weak link of Le Chatelier's theorem applied quite out of context. The present investigation shows that in one third of the genera studied the drier-living species has, in fact, the larger cells, cells sometimes of nearly double volume. The issue has been bedevilled by polyploidy. But thanks to the collateral progress of nuclear cytology[10,2], it can now be unscrambled. Thus, for the material here studied, we can at least definitely state that the drier-living species have inherently in their laminas (i) drier cells, and (ii) cells which have a smaller volume per chromosome.

Without dealing with the various other points which arise, a picture begins to emerge of the selection by ecological dryness of genotypes with the following characters: less dilate and usually thinner laminas, but which usually contain a greater dry weight, a greater number of cells and a greater total number of chromosomes; and less dilate cells, in which each chromosome is associated with a smaller amount of dry matter and water and a smaller cell volume—cells in which unit dry weight contains apparently a higher proportion of genes.

It is perhaps not inappropriate to find it reported that these species of intrinsically less-favourable habitats have cells which are relatively the better equipped with molecular-level 'machine-tools'; while in moister habitats other species, less heavily equipped, are able to displace them. On a rough analogy, the maintenance workshops and equipment which supported Sir Vivian Fuchs's crossing of Antarctica would be out of place in a walking tour along the Pennines.

β-Globulin Variants in Man

USING starch-gel electrophoresis, Smithies has discovered several β-globulin patterns in human plasma. He refers to these as β*C*, β*BC*, β*CD* and β*D*[1,2]. β*C* is the type most commonly found, but β*BC* occurred in about 1 per cent of Canadians and β*CD* in about 4 per cent of American Negroes and even more frequently in Australian Aboriginals. The formation of the different β-globulins *B*, *C* and *D* appears to be genetically controlled and Smithies suggests that each may be determined by one of three allelic genes.

In a search for such β-globulin types we have recently encountered four unusual patterns. The starch-gel electrophoresis was carried out on plasmas to which hæmoglobin had been added to saturate the haptoglobins, using the discontinuous buffer system of Poulik[3]. Under these conditions the β-globulin region is clear of either the hæmoglobin – haptoglobin complexes or free hæmoglobin (Fig. 1) and it is possible to pick out unusual β patterns in one-dimensional separations. The unusual plasmas were further subjected to two-dimensional paper/starch-gel electrophoresis[4] to confirm the identification of the new components as β-globulins.

In a series of 153 Africans from Gambia we observed four individuals who had, besides β-globulin *C*, a slower moving β-globulin component which was present in about the same amounts as β-globulin *C*. In one of these individuals, however, the unusual β-globulin component had a distinctly slower mobility than that found in the other three. Thus two distinct β-globulin variants appeared to be present in this African population, and since it is probable that one of these corresponds to the β-globulin *D* of Smithies we will refer to them for the present as β-globulins D_1 and D_2 (Fig. 1).

In a series of 139 English people no example of phenotypes βCD_1 or βCD_2 was observed. However, two individuals were encountered with an unusual β-globulin component moving faster than β-globulin *C*. In both, the new component was present along with, and in about equal amounts to, β-globulin *C*. The mobility of the new fast-moving component was, however, different in the two individuals (Fig. 1). Since one of them probably corresponds to Smithies' β-globulin *B* we will refer to these two new components as β-globulins B_1 and B_2.

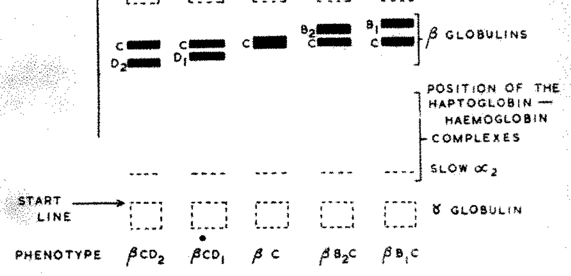

Fig. 1. Relative mobilities of β-globulin variants in human plasma. (Starch-gel electrophoresis with the discontinuous buffer system of Poulik)

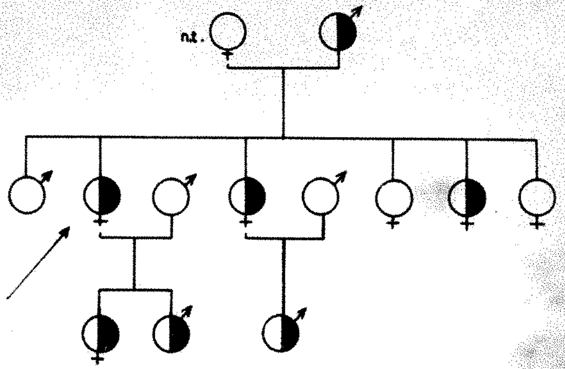

Fig. 2. Pedigree of family *W*. β-globulin phenotypes: ○, β*C*; ◑, βB_1C; *n.t.*, not tested

Among the relatives of the individual with phenotype βB_1C six further individuals were encountered with the same phenotype. The pedigree is shown in Fig. 2, and it seems reasonable to infer that the formation of β-globulin B_1 is genetically determined and that the individuals in this family with the βB_1C phenotype are heterozygous for the appropriate gene.

So far it has not been possible to carry out family studies on any of the other variants observed. However, these results, combined with those of Smithies[2], suggest that a whole series of genetically determined β-globulin variants can occur and the situation may well prove to be analogous to that found with respect to the genetically determined hæmoglobin variants which have been so extensively studied in recent years.

We would like to thank Dr. J. Humphries, who kindly put at our disposal the samples from the population in Gambia.

High Resolution of Human Plasma Components by Starch Gel Electrophoresis

WITH one-dimensional starch gel electrophoresis, the following experimental procedure allows the separation of human plasma into a large number of components.

The gel is poured into 'Plexiglas' trays (internal dimensions 370 mm. × 50 mm. × 20 mm.). The sample (a mixture in equal parts of plasma and 30 per cent soluble starch in 0·025 *M* borate buffer) is applied in a slot, 40 mm. × 2 mm. Electrical connexion with the ends of the gel is obtained by means of thick filter paper ('Cofram' *MAB C* 3).

A potential of 450 V. is applied for 18 hr. at +4° C. After electrophoresis, the gels are fixed in

5 per cent acetic acid and stained with aqueous amido-black (amido-black 10 *B*, 1 gm.; 1 *M* acetic acid, 500 ml.; 0·1 *M* sodium acetate, 500 ml.). The gel is then washed with 5 per cent acetic acid.

The electrophoretic pattern obtained with a haptoglobin type 2 (*Hp* 2) human plasma is shown in Fig. 1; on the cathodic side of the slot, two γ-globulin zones; on the anodic side, from the slot towards the albumins, first are seen two zones, one being a β-lipoprotein (which stains with sudan black); then the $S\alpha_2$-globulin band, then nine strips between the $S\alpha_2$- and the βc-globulin, three of them being characteristic of *Hp* 2–1 and *Hp* 2–2 groups; then βc-globulin, one or two $F\alpha_2$-globulins, five strips between the fast α_2 and the albumin border and finally albumin.

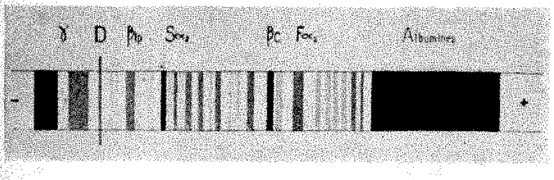

Fig. 1

The recent results obtained by Poulik and Smithies[1] with two-dimensional starch gel electrophoresis define the nature of the zones we have just described. We believe that among the five strips between the albumin and the fast α_2-globulins some correspond to the α_1-globulins (α_1A or α_1B).

The βc globulins are preceded by a zone which may be a β component (β*A* or β*B*).

Besides this large tray technique we have used a standard method involving smaller 'Plexiglas' trays (internal dimensions 234 mm. × 80 mm. × 6 mm.) for the study of different protein solutions. Two samples are applied in two slots (28 mm. × 2 mm.) and allowed to migrate simultaneously, side by side, in the same tray for 18 hr. with a 140 V. potential. Electrophoretic patterns under these conditions are similar to those obtained by Smithies[2]; however, the γ-globulin zone is distinctly divided into two components. In macroglobulinæmia an increase in the fast or the slow component can occur.

A New Method for resolving Amino-acids by Metabolism of Bacteria on Benzoyl Derivatives of DL-Amino-acids

While engaged in the study of metabolism and hydrolysis by soil bacteria of benzoic acid derivatives, amino-acids, and acylated amino-acids[1–4], we noticed that soil bacteria *KT* 231 and *KT* 233 have the metabolic activity shown in Table 1. The constituents of the culture medium used in the experiments were as follows: NH_4Cl, 0·1 gm.; K_2HPO_4, 0·1 gm.; $MgSO_4.7H_2O$, 0·05 gm.; 1 per cent $CaCl_2.6H_2O$, 2 drops; 1 per cent $FeCl_3.6H_2O$, 1 drop; organic substance to be tested, 0·2 gm.; distilled water, 100 ml.; *p*H 7·4–7·6 (adjusted with 10 per cent sodium hydroxide).

Table 1

	KT 231	*KT* 233		*KT* 231	*KT* 233
Benzoic acid	+	+			
Dibenzoyl-DL-lysine	+	+	Benzoyl-DL-leucine	+	+
Dibenzoyl-DL-lysine (without NH_4Cl)	–	–	Benzoyl-DL-leucine (without NH_4Cl)	–	+
Dibenzoyl-D-lysine	–	–	Benzoyl-D-leucine	–	–
ε-N-Benzoyl-DL-lysine	–	–	DL-Leucine	–	+
Benzoyl-DL-phenylalanine	+	+	N-Benzoyl-DL-threonine	–	+
Benzoyl-DL-phenylalanine (without NH_4Cl)	–	+	N-Benzoyl-DL-threonine (without NH_4Cl)	–	–
Benzoyl-D-phenylalanine	–	–	N-Benzoyl-D-threonine	–	–
DL-Phenylalanine	–	+	DL-Threonine	–	–

+, Within four days at 25° C. there were luxuriant growths of bacteria on a culture medium with the particular organic compound as the source of carbon. This cultivation experiment was repeated three times in succession.

–, No visible growth of bacteria observed.

From the left column of Table 1, it is to be understood that *KT* 231 and *KT* 233 can utilize benzoic acid, which was produced from dibenzoyl-L-lysine by the action of their acylases, as the sole source of carbon. The ability of *KT* 231 to resolve dibenzoyl-DL-lysine was then tested as follows: *KT* 231 was grown at 25° C. in 100 ml. of the culture medium mentioned above containing 2·67 gm. of dibenzoyl-DL-lysine. After 3 days, the culture medium was adjusted to *p*H 4·5 with acetic acid, evaporated *in vacuo* to a small volume, acidified with dilute hydrochloric acid to *p*H 1·0, and extracted with ethyl acetate. From the aqueous layer, 0·80 gm. (85·0 per cent) of ε-N-benzoyl-L-lysine, m.p. 270–272° C. (decomp.), $[\alpha]^{20}_D = +19°$ was obtained. From the ethyl acetate layer, 1·08 gm. (81·5 per cent) of dibenzoyl-D-lysine, m.p. 145–146° C., $[\alpha]^{20}_D = +7·5°$ and 0·03 gm. (6·5 per cent) of benzoic acid, m.p. 118–120° C. were obtained.

In the same way, *KT* 231 metabolized benzoyl derivatives of DL-phenylalanine and DL-leucine to yield the following compounds respectively: L-phenylalanine, $[\alpha]^{18}_D = -35°$, benzoyl-D-phenylalanine, m.p. 139–140° C., $[\alpha]^{18}_D = -15°$ and L-leucine, $[\alpha]^{20}_D = +15°$, benzoyl-D-leucine, m.p. 103° C., $[\alpha]^{20}_D = +9·5°$. By the metabolism of *KT* 233, L-threonine, $[\alpha]^{20}_D = -28°$, and N-benzoyl-D-threonine, m.p. 145–146° C., $[\alpha]^{20}_D = -25°$, were obtained from *N*-benzoyl-DL-threonine in good yield.

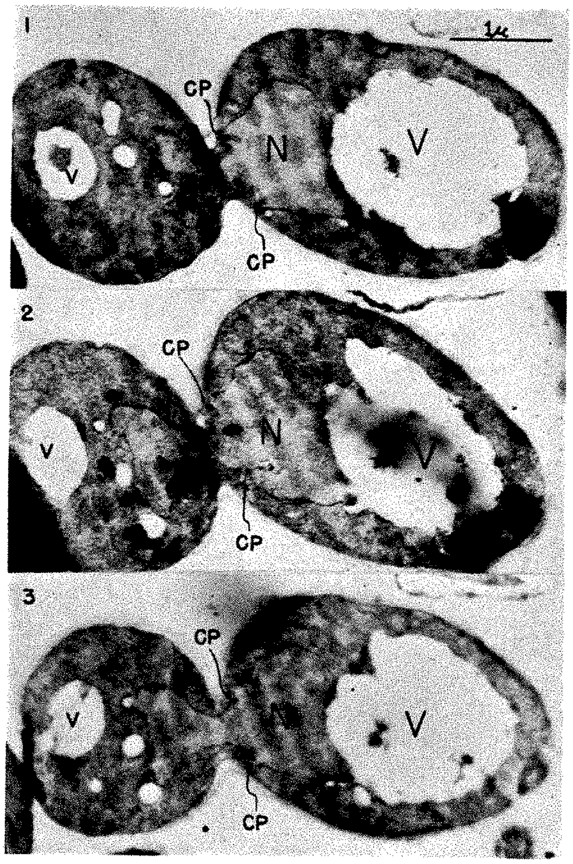
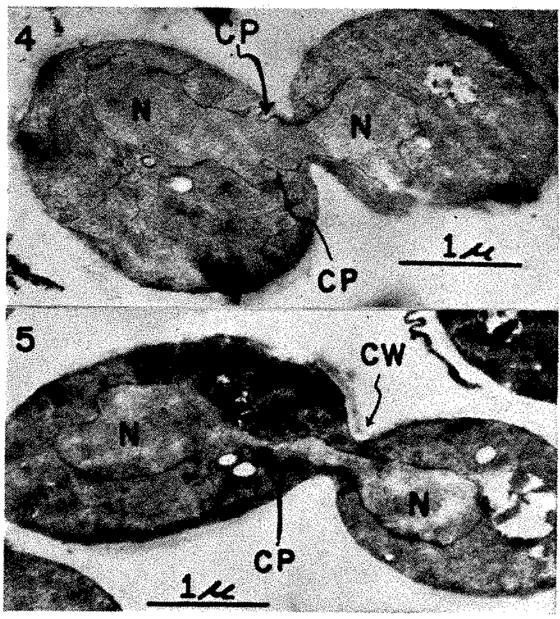
Nuclear Changes occurring during Bud-formation in *Saccharomyces cerevisiae* as revealed by Ultra-thin Sectioning

The lack of clarity prevailing among yeast cytologists as to the mode of budding in *Saccharomyces cerevisiae* tempted us to study this process by means of an improved ultra-thin sectioning technique. This technique has enabled us to observe nuclear behaviour during bud formation and subsequent division. Except for substitution of potassium permanganate for osmium tetroxide as the fixative, the method of preparing specimens for ultra-thin sections was exactly the same as previously reported[1,2]. A distillers yeast, *S. cerevisiae M*-1, was grown in a broth medium for several hours at 25° C. with aeration by means of vigorous shaking. The cells were collected by centrifugation and washed once with distilled water. The washed cells were then fixed in a 1·5 per cent aqueous solution of potassium permanganate at room temperature for 30 min. The time of fixation and concentration of permanganate were critical for preservation of internal cell structure. Explosion was minimized by prolonged treatment of the cells with cold partially polymerized *n*-butyl methacrylate. The sections were cut on a Porter–Blum microtome and observed in an *RCA* model *EMU-2b* electron microscope. Figs. 1, 2 and 3 show three parallel sections of a budding yeast cell. It is interesting that the conspicuous invagination of the dividing nucleus is situated a short distance away from the constricted cell wall of the bud. The difference in the planes of constriction between the nucleus and the cell wall seems to be a routine occurrence and is considered characteristic of vegetative division in *S. cerevisiae*. This suggests that there is some mechanism which regulates the constriction of the nucleus at this point other than the simple pressure of the constricting cell wall. Close observation of these figures reveals that the constriction starts at certain points rather than being initiated uniformly around the site of constriction. The presence of the nuclear membrane throughout vegetative nuclear division implies that typical mitosis in *S. cerevisiae*, at least in the strict sense of the word, is lacking. Chromosomal figures which have been observed in the nuclei of the cells of higher organisms[3-5] have not been detected in either the nuclear vesicle or on the nuclear membrane during any stage of the nuclear division. Figs. 4 and 5 demonstrate somewhat later stages of nuclear division during bud-formation.



Figs. 1–3. A budding yeast cell. *N*, nucleus; *CP*, constriction point; *V*, vacuole; *CW*, cell wall



Figs. 4–5. Budding yeast cells at a later stage. Key as in Figs. 1–3

From the observations made in this study, we conclude:

(1) The nuclear membrane of *Saccharomyces cerevisiae* does not disappear during vegetative division. This favours the view that division of the nucleus during budding does not occur by a typical mitotic process.

(2) The nucleus of *Saccharomyces cerevisiae* undergoes an autonomous constriction during bud formation. Constriction of the nucleus does not coincide with constriction of the cell wall, but always occurs a little inside the mother cell.

Heinz Bodies in Extravasated Erythrocytes

In many cases of toxic anæmia refractile granules, generally known as Heinz bodies, are formed in the red blood cells. These inclusions may be identified by their intense basophilia when stained supravitally; after fixation with alcohol they lose this property and as a result are not usually seen in Romanowsky-stained blood films. In these anæmias there is an associated fragmentation and distortion of the red blood cells.

A similar type of fragmentation and distortion of the red cells is sometimes seen in hæmothorax fluids, and this led us to examine the red cells by supravital staining with methyl violet. By this means Heinz bodies were demonstrated in the majority of serous and cystic fluids, and sometimes in bloodstained cerebrospinal fluid as well.

The inclusions show similar features to those of Heinz bodies formed in the circulating blood. They may be seen as refractile particles in unstained wet preparations and rapidly assume a dark purple-black colour when stained supravitally with 0·5 per cent methyl violet in normal saline. They vary in size from the minutest of dots to structures 3μ in diameter, and irregularly shaped forms may be seen as well as more rounded inclusions. An affected red cell may contain a single inclusion or a number (Fig. 1).

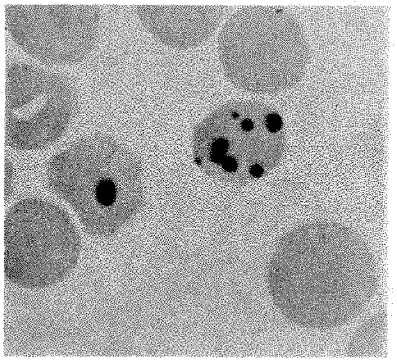

Fig. 1. Heinz bodies in erythrocytes in pleural fluid

The affected red cells may be otherwise normal in appearance, although often the inclusions are also found in distorted or spherocytic cells. In some specimens the red cells show a greater variety of appearances than red cells from the circulating blood in Heinz body anæmia.

Table 1 classifies 121 specimens from 100 patients, grading the extent of Heinz body formation in three categories.

In 15 cases more than one specimen was examined over a period of time. In six cases the proportion of cells containing Heinz bodies rose; for example, in a case of hæmothorax following mitral valvotomy there were 1·5 per cent 9 days after operation, less than 0·5 per cent at 24 days, 2 per cent at 28 days and 10 per cent 37 days following the operation. In one case an increase was later followed by a decrease; in seven cases no appreciable difference in the proportion of Heinz body containing cells was observed; and in two cases only a decrease was found.

Table 1

	Percentage of red cells containing Heinz bodies			
	>5·0	0·5–5·0	< 0·5	Total
Pleural and peritoneal fluids	19	40	32	91
Cysts, hydrocœles, joints and bullæ	2	5	4	11
Hæmatomas	1	6	1	8
Cerebrospinal fluid	4	6	1	11
Total	26	57	38	121

We consider that the finding of red cells containing Heinz bodies in so high a proportion of fluids examined indicates that this is a normal step in the breakdown of red cells which have been shed into the body cavities. In old collections of blood the affected corpuscles are very numerous. For example, in a subdural hæmatoma of 3 weeks standing 70 per cent of the red cells were affected; in a pseudomucinous ovarian cyst 85 per cent, and in a dental cyst of the maxilla 100 per cent of the red cells contained Heinz bodies. In such cases as these the cells show complete loss of hæmoglobin and the inclusions become fixed to the distorted cell membrane. However, in serous cavities from which extravasated red cells are usually absorbed rapidly, such as the pleural and peritoneal spaces, cells containing Heinz bodies are often very scarce.

Although there are a number of reports[1-4] that similar inclusions are formed when red blood cells are incubated *in vitro* under sterile conditions, we have found only one case report in the literature of this century[5], in which Heinz bodies were noted in extravasated red cells *in vivo*. The phenomenon was, however, known to Virchow, and is described in the first volume of his *Archives*[6], but seems to have been since forgotten. Experiments by one of us (R. S. S.) are now in progress to follow the process of Heinz body formation in shed blood, and the results will be published later.

Antibiotic Substances from Yeast

It was suggested[1] that the micro-organism-inhibiting properties of material from baker's yeast reported by us[2] might lie in a mixture of fatty acids. Although we had found that fatty acids from yeast could inhibit the respiratory metabolism of yeast and tissues[3] we believed that other types of substances might be involved.

The following preparative procedure was finally used. Twenty-five pounds of baker's yeast were extracted with 95 per cent ethanol under reflux for 5 hr. The extract was taken to dryness *in vacuo* and 100 ml. of water were added. After filtration, the aqueous filtrate was acidified to pH 2 with 0·1 N hydrochloric acid and extracted with ether. The ether was removed and the residue was dissolved in water and adjusted to *p*H 6. The aqueous solution was extracted with ether and the ether discarded. The aqueous solution was adjusted to *p*H 4 and again extracted with ether. The ether solution was concentrated and placed in one strip on Whatman No. 3 *MM* paper. The ascending chromatogram was developed with water/pyridine/ethyl acetate (400 : 180 : 400). After spraying with ammonium hydroxide, a strip containing material which fluoresced yellow under ultra-violet light could be cut out. The material was eluted with ethanol and the concentrated eluate was chromatographed by the descending technique, using ethanol/water/ammonium hydroxide (80 : 15 : 5) as the solvent. After spraying the paper with ammonium hydroxide, ultra-violet light revealed two strips, *Y*1 with R_F 0·5, and *Y*2 with R_F 0·7. Each was eluted separately with ethanol and the concentrated eluates were separately chromatographed by the ascending technique in water/pyridine/ethyl acetate. Both substances, in yields of about 30 mgm., were colourless, soluble in warm ethanol, and chromatographically pure. They could not be crystallized. They did not give colour reactions on chromatograms with ninhydrin, diazotized sulphanilic acid, Ehrlich's reagent, or cyanogen bromide. Attempts to obtain derivatives with 2,4-dinitrofluorobenzene and picric acid failed.

After hydrolysis with hydrochloric acid, *Y*1, in two-dimensional chromatograms with the solvents phenol saturated with a solution of 6·3 per cent sodium citrate and 3·7 per cent potassium dihydrogen phosphate[4], and butanol/acetic acid/water (4 : 1 : 1)[5], revealed leucine, valine, alanine, glutamic acid and glycine. *Y*2 gave the same amino-acids and, in addition, γ-aminobutyric acid.

Paper electrophoresis in phosphate buffers at *p*H's of 2, 4, 7 and 12 in all cases resulted in migration towards the anode, migration being most rapid at *p*H's 2 and 12. *Y*1 moved faster than *Y*2.

*Y*1 in acetone gave only a low ultra-violet cut-off. *Y*2 had an absorption peak at 255 mμ. γ-Aminobutyric acid gave only end absorption, but after standing in 2·5 per cent concentration in 0·1 per cent hydrochloric acid for a week slight absorption developed at 270 mμ. Infra-red absorption spectra of films on potassium bromide showed both compounds to absorb at approximately 3·0μ, 3·4μ, 5·95μ, 6·1μ (*Y*1), or 6·2μ (*Y*2), and 6·9–7·0μ; *Y*2 also had slight absorption at 8·0μ.

Antibacterial activity of all preliminary fractions as well as of *Y*1 and *Y*2 was determined *in vitro* against *Micrococcus pyogenes*, var. *aureus* by the filter disk method. Some of the fractions were also assayed against the moulds *Aspergillus niger* and *Penicillium glaucum*, and found to be effective. *Y*1, in a concentration of 1 mgm. per disk, produced a 1 cm. zone of complete inhibition of *M. pyogenes* in 24 hr. *Y*2, in a concentration of 0·5 mgm. per disk, gave a similar inhibition. γ-Aminobutyric acid has been shown to be inactive against the organism[6].

The compounds appear to be peptides, and since no free amino-groups have been detected, possibly cyclic peptides. *Y*1, somewhat more electronegative than *Y*2, seems to differ from *Y*2 only in the absence of γ-aminobutyric acid. γ-Aminobutyric acid has been isolated from yeast extract in the free state and has been considered to be a degradative product[5]. Our results suggest but do not prove that the acid may be a constituent of a peptide. Structural considerations obviously will depend upon future analytical studies.

Recombination Ability of *Escherichia coli* *K*-12 Protoplasts

SINCE Repaske's[1] and Lederberg's[2] discoveries, protoplasts of *Escherichia coli* have formed useful material for biosynthetic and genetic studies, for example, in *T*-2 phage multiplication[3,4], in rehabilitation of a deficient mutant[5] and, more recently, in recombination behaviour[6]. During the past two years great advances have been made in our understanding of genetic recombination in *E. coli*, especially through the finding that genetic material is transferred from *F*+ donor into *F*− recipient cells[7-9]. In these situations, genetic recombination between *E. coli* protoplasts was attempted in order to obtain further information on the properties of protoplasts and the process of genetic recombination.

Cells of *E. coli* *K*-12 58–161 *F*+ in the stage of logarithmic growth were protoplasted with 100 μgm./ml. lysozyme and 0·3 mgm./ml. ethylenediamine tetraacetic acid (versene) in a solution of 30 m*M* *tris* buffer and 0·6 *M* sucrose at *p*H 7·8. Protoplasts of *E. coli* were suspended in phosphate buffer (*p*H 7·2) supplemented with 20 μ*M* glucose and 200 μgm./ml. sodium aspartate with and without stabilizer. In the former solution protoplasts were well stabilized (experiment 1) and in the latter they were osmotically shocked and a viscous lysate was obtained to which the same amount of stabilizer was added (experiment 2). The controls were unprotoplasted cells handled identically except for the omission of lysozyme and versene (experiment 3 vs. experiment 1 and experiment 4 vs. experiment 2). These four preparations were mated for 2 hr. at 37° C. with intact *Y*-70 *F* − recipient cells requiring threonine, leucine and thiamine) and then plated on *EMS* medium. Various kinds of stabilizers were tested to ascertain whether they could support the protoplasts and their recombination. It was shown that 0·6 *M* sucrose was the most appropriate stabilizer for this purpose ; others, such as disodium hydrogen phosphate and sodium and potassium chlorides, sodium succinate, etc., inhibited recombination in spite of their efficient stabilizing effect. Table 1 shows a typical experiment illustrating the formation of recombinants in phosphate buffer

Table 1. RECOMBINANT FORMATION FROM *Y*-70 *F*− CELLS MATED WITH 58-161 *F*+ PROTOPLAST AND LYSATE PREPARATIONS

Exp.	*F*−	× *F*+	No. of recombinants
1	Unprotoplasted	protoplasted	109
2	Unprotoplasted	protoplasted, lysed	42
3	Unprotoplasted	unprotoplasted	179
4	Unprotoplasted	unprotoplasted, lysed	190

Table 2. DIFFERENTIAL CENTRIFUGATION OF PROTOPLASTED AND UNPROTOPLASTED CELLS

Speed in r.p.m. Percentage recovery of protoplast		1,000 94	2,000 5	3,000 1
			No. of recombinants*	
F− ×	*F*+			
Unprotoplasted	protoplasted	128 (1·4 × 10⁶)	16 (3·4 × 10⁶)	0 (1·0 × 10⁶)
Unprotoplasted	protoplasted, lysed	16 (1·0 × 10⁶)	16 (3·2 × 10⁶)	0 (1·0 × 10⁶)
Unprotoplasted	unprotoplasted	92 (1·1 × 10⁸)	40 (3·1 × 10⁸)	12 (2·4 × 10⁸)

* Figures in parentheses indicate the intact bacterial count per ml. remaining in each fraction.

stabilized with sucrose and supplemented with glucose and aspartate.

This suggested that some but not all of the recombinants were formed at the protoplast level, because the number of recombinants was decreased if the protoplasts were lysed by osmotic shock as in experiment 2. The difference between experiments 1 and 2 was smaller than the initial expectation, but this may be due in part to the slight increase between experiments 3 and 4. In every experiment, of course, intact cells which had not been affected by lysozyme remained in the protoplast and lysate preparations and participated to some extent in the formation of recombinants. However, the number of recombinants which appeared were much in excess of the number expected to arise from residual intact cells at the normal recombination rate ($1 \cdot 4 \times 10^{-8}$ in phosphate buffer). This remains, however, to be studied in detail.

The implications of these experiments were supported by certain differences in behaviour during centrifugation between protoplasted and unprotoplasted cells. Most of the protoplasts formed were easily collected by low-speed centrifugation. About 94 per cent of the protoplasts were deposited in 10 min. at 1,000 r.p.m., and when the supernatant from this first centrifugation was spun again at 2,000 r.p.m., a further 4 per cent of the protoplasts were recovered in the deposit. Each of these was mated directly or after being lysed by dilution with the unprotoplasted *F*− cells as in the method described earlier.

This experiment showed that the fraction which yields most of the recombinants coincides with that in which most of the protoplasts were recovered.

The reciprocal cross was made in which *Y*-70 *F*− cells were protoplasted and mated with intact 58–161 *F*+ cells in a similar procedure to that described above.

If the recipient *F*− cells were protoplasted and lost their capacity for further cell division, recombinant formation would have been inhibited completely. In fact, however (Table 3), a number of recombinants appeared. If all the *F*− protoplasts were lysed, they presumably could not have acted as recipient cells and yielded recombinants. The 32 recombinants, therefore, must have arisen from mating of the unprotoplasted *F*+ cells with residual *F*− cells, and their recombination-rates were increased by the liberation of a nutrient material from the products of lysing protoplasts.

Table 3. RECOMBINANT FORMATION FROM 58-161 *F*+ CELL MATED WITH *Y*-70 *F*− PROTOPLAST AND LYSATE PREPARATIONS

Exp.	*F*− ×	*F*+	No. of recombinants
5	Protoplasted	unprotoplasted	42
6	Protoplasted, lysed	unprotoplasted	32
7	Unprotoplasted	unprotoplasted	115
8	Unprotoplasted, lysed	unprotoplasted	120

Table 4. RECOMBINANT FORMATION FROM PROTOPLAST AND LYSATE PREPARATIONS

Exp.	*F*− ×	*F*+	No. of recombinants
9	Protoplasted	protoplasted	112
10	Protoplasted	protoplasted, lysed	65
11	Protoplasted, lysed	protoplasted	9
12	Protoplasted, lysed	protoplasted, lysed	4

Further support was obtained from alternative crosses in which both *F*+ and *F*− protoplasts were mated directly (experiment 9), either *F*+ or *F*− protoplasts were shocked and mated with *F*− or *F*+ protoplasts respectively (experiments 10 and 11), and both were shocked and mated together (experiment 12).

These results indicate the one-way transfer of genetic material from *F*+ to *F*− cells; the appropriate compatibility-type of donor and recipient is required even in the subcellular level. But the question remains whether *F*− protoplasts which could not divide further by themselves acquired the ability to revert and to form normal colonies after mating with *F*+.

These results with *E. coli* protoplasts illustrate the possibility of a new approach to the study on the mechanism of bacterial recombination and transformation.

I am indebted to Prof. H. Kikkawa and Dr. Y. Hirota for their suggestions and criticism, and to Mr. T. Iijima for his advice and encouragement.

Effects of Flavin Monosulphate and Flavin Adenine Dinucleotide on the Electroencephalogram

FLAVIN MONOSULPHATE (riboflavin-5′-monosulphate) has been found to inhibit D-amino-acid oxidase in competition with flavin adenine dinucleotide[1]. On the other hand, it was supposed that flavin adenine dinucleotide might have some important role in the brain since it reversed the inhibitory action of chlorpromazine on the oxidation of amino-acids by a homogenate of the diencephalon part of the brain[2]. Taking these results into consideration, the effects of flavin monosulphate and flavin adenine dinucleotide on the function of the brain were examined by electroencephalography.

Flavin monosulphate was synthesized by sulphonation of riboflavin dissolved in pyridine using chlorosulphonic acid at 40° C., in dry conditions. The flavin monosulphate was purified by powdered

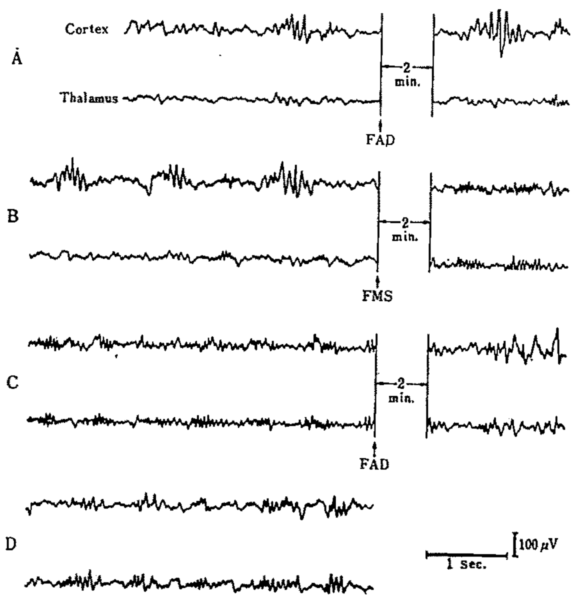

Fig. 1. Effects of the successive injection of flavin adenine dinucleotide and flavin monosulphate on the electroencephalogram. (*A*) Corticogram and depth electroencephalogram from the thalamus before and after the administration of flavin adenine dinucleotide; (*B*) the effect of the administration of flavin monosulphate on the continued electroencephalogram of (*A*); (*C*) the effect of the second administration of flavin adenine dinucleotide on the continued electroencephalogram of (*B*); (*D*) continued electroencephalogram of (*C*)

cellulose chromatography, and finally the calcium salt of flavin monosulphate was obtained as yellow crystals[3]. Flavin adenine dinucleotide was prepared by the method of Yagi *et al.*[4]. Its purity was more than 92 per cent, and other flavins, nucleic acids or metals were not present. Each flavin compound was used as an aqueous solution containing $0 \cdot 25 \times 10^{-6}$ mol./ml.

A guinea pig was narcotized by the intra-abdominal injection of urethane. After craniotomy, two kinds of electrode were placed on the brain; one was on the surface of the cerebral cortex to record the corticogram, and the other was put into the thalamic region to record the depth electroencephalogram. The exact position of the depth electrode was checked by histological examination of the brain after the experiment. The reference electrode was put on the frontal area of the cranium, and the monopolar leads were taken between the reference electrode and the cortex or the thalamic region. For recording, a Grass Model III *D* electroencephalograph was used. When a stable electroencephalogram was obtained, 2 ml. of an aqueous solution of flavin monosulphate or flavin adenine dinucleotide ($1 \cdot 0 \times 10^{-6}$ mol./kgm. of animal) were injected intra-abdominally, and the changes in the electroencephalogram were observed.

After the injection of flavin adenine dinucleotide, the voltage increased in both electroencephalograms. The characteristic change was observed in the corticogram: a slow wave of high voltage in spindle form appeared periodically. On the other hand, after the injection of flavin monosulphate, fast activity of 20–25 c./s. was observed in both electroencephalograms, and the voltage did not increase, but slightly decreased.

The changes in both electroencephalograms after the successive administration of flavin adenine dinucleotide and flavin monosulphate are shown in Fig. 1. By the administration of flavin adenine dinucleotide, the changes mentioned above were observed as shown in Fig. 1 *A*, *B*. 15 min. after the injection, flavin monosulphate was injected, and the remarkable fast activity appeared in both electroencephalograms (Fig. 1 *B*, *C*). Then, 15 min. later, flavin adenine dinucleotide was injected again, and the voltage increased in each electroencephalogram and the frequency decreased (Fig. 1 *C*, *D*). From these results, it seems that flavin adenine dinucleotide and flavin monosulphate have opposite effects on the electroencephalogram to each other.

The effects of free riboflavin and adenosine monophosphate were also examined. Free riboflavin did not cause any change on the electroencephalogram. Adenosine monophosphate had a tendency to increase the voltage, but this change was less than that due to flavin adenine dinucleotide, and the spindle forms were not observed. The effect of calcium ions at a concentration equivalent to that in the aqueous solution of flavin monosulphate calcium salt was also examined, and the result showed no characteristic change.

It is interesting to see that the antagonistic action of two flavin compounds found in the pure enzyme system was also observed in functional phenomena such as the electroencephalogram.

Activation of an Ascorbic Acid Concentrating Mechanism by Some Corticosteroids *in vitro*

A RELATION between the actions of ascorbic acid and certain corticosteroids has often been indicated[1]. Since considerable evidence has accumulated that steroid hormones may act by altering the permeability of the cell membrane to a given compound[2] this relationship may be the result of changes in the permeability of certain cellular membranes to ascorbic acid as a result of the action of certain corticosteroid hormones.

To examine this possibility the following experiment was carried out. Six male rats of the Long–Evans strain weighing 250–300 gm. were maintained on a 60 per cent glucose diet[3] for three days. They were then killed, their livers rapidly removed and slices $0 \cdot 5$ mm. thick were prepared. 1 gm. of slices was incubated in 5 ml. of Krebs–Henseleit bicarbonate buffer[4] (*p*H $7 \cdot 3$–$7 \cdot 4$) containing 200 mgm. per cent glucose with or without 25 mgm. per cent of the hormone indicated. Complete solubility was not obtained with either hormone, but they were kept

Table 1

Animal	Flask	Hormone	Ascorbic acid diffusing into media per gm. of liver (μgm.)	Decreased diffusion of ascorbic acid per gm. of liver (μgm.)*
1	1*A*	None	202	25
	1*B*	Hydrocortisone	177	
2	2*A*	None	177	34
	2*B*	Hydrocortisone	143	
3	3*A*	None	178	25
	3*B*	Hydrocortisone	153	
4	4*A*	None	280	74

	7*B*	Cortisone	172	
6	8*A*	None	216	37
	8*B*	Cortisone	179	
	9*A*	None	191	41
	9*B*	Cortisone	150	

* Standard deviation = ± 20

well dispersed while being pipetted. In all cases the liver slices in the flasks of a given number were prepared from the same liver lobe of the animal. At the end of 3 hr. incubation at 37° in an atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide, a 3 ml. sample of the medium was removed and the protein precipitated with 12 ml. of 5 per cent trichloracetic acid. The ascorbic acid was then determined in duplicate for each flask by the method of Roe and Kuether[5]. Tests with standard amounts of ascorbic acid in the presence and absence of cortisone indicated that the hormone had no effect on the ascorbic acid determination. The results are shown in Table 1 and indicate a decreased diffusion of ascorbic acid in the presence of either hormone.

A possible explanation for this phenomenon is the activation of a mechanism for concentrating ascorbic acid by the hormones, either at the cell membrane or at some intracellular site.

Since there is evidence that ascorbic acid is essential to the animal cell for the maintenance of ferrous ions and thus for the continued operation of the citric acid cycle (aconitase) and other reactions dependent on ferrous ions[6], many of the metabolic roles of these corticosteroids may be exerted indirectly by increasing the intracellular concentration of ascorbic acid with the resultant activation of these metabolic reactions based on ferrous ions. A possible permeability barrier to ferrous ions or ascorbic acid or both at the mitochondrial membrane has been postulated[6]. The existence of such a barrier would necessitate an active transport mechanism.

Furthermore, there is evidence that a progressive increase in the production of corticosteroids occurs with increasing ascorbic acid deficiency in guinea pigs[7]. Hence the proposed mechanism may be involved in a homœostasis for the maintenance of optimal intracellular ascorbic acid and the continued operation of fundamental *in situ* cellular reactions dependent on ascorbic acid.

The above mechanism may also play a part in the activation reactions yielding energy associated with adaptation to stress. During stress tissues require greater amounts of ascorbic acid[1] and the increased secretion of corticosteroids that occurs during stress[1] may be a response that is essential to the transfer of this increased ascorbic acid to the intracellular sites where its actions occur.

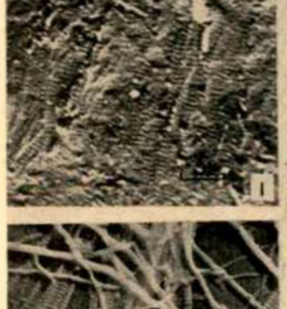
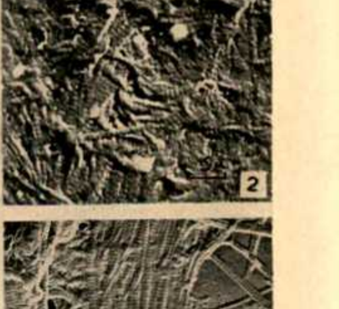
Collagen in Human Cementum as shown by Electron Microscopy

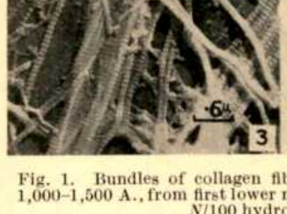
ELECTRON microscopy has been used extensively in the study of collagen in skin, tendon and cartilage. Its presence in bone has also been shown by several workers, including Huber and Rouiller[1] and Randall *et al.*[2]. Ascenzi[3], in addition to his own observations, discusses critically the literature on the structure of bone as demonstrated by electron-microscope techniques.

Examination of cementum matrix with the light microscope, using decalcified preparations selectively stained and ground sections of teeth, suggests that it contains collagenous fibres. In view of the close resemblance of cementum to bone as a calcified connective tissue, this investigation was undertaken to ascertain whether collagen fibrils could be demonstrated in human cementum using electron micrography.

Molar teeth extracted from young adults with no clinical disease of the cementum were washed in normal saline and then fixed in formalin. The teeth were bisected in the mesio-distal plane and the interior surface of the inner half polished and etched with *N*/100 hydrochloric acid. The structure of







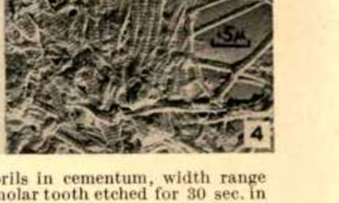


Fig. 1. Bundles of collagen fibrils in cementum, width range 1,000–1,500 A., from first lower molar tooth etched for 30 sec. in *N*/100 hydrochloric acid

Fig. 2. Interlacing collagen fibrils in cementum, width range 300–850 A., from first lower molar tooth, etched for 30 sec. in *N*/100 hydrochloric acid

Fig. 3. Shadowed teased preparation of tendo-calcaneus

Fig. 4. Shadowed carbon replica of tendo-calcaneus

cementum from each of the roots was examined by electron microscopy using gold-palladium pre-shadowed negative carbon replicas taken from the prepared surface.

In all the specimens examined fibrils exhibiting the characteristic 640 A. periodicity of collagen were observed. Broad bundles of fibrils (Fig. 1) having a width in the range 1000–1500 A. were observed. Interlacing fibrils (Fig. 2) were also seen throughout the cementum matrix with a width of 300–850 A.

Fig. 3 shows a shadowed teased preparation and Fig. 4 illustrates a shadowed carbon replica of collagen from the tendo-calcaneus.

The periodicity of the fibrils found in the cementum is 640 A., being the same as that of the collagen from the tendo-calcaneus.

All the material used and illustrated was obtained from women in the age group 20–22 years.

An Abnormal Hæmoglobin in a Chinese : Hæmoglobin *G*

It has been known for many years that thalassæmia exists among the Chinese. Hæmoglobin *H* was discovered in a Chinese family[1] and has since been seen repeatedly in other Chinese families[2,3]. Thus in Singapore, over a period of fifteen months, 15 unrelated Chinese patients with anæmia were examples of hæmoglobin *H* disease. Another hæmoglobin, *Q*, has so far been observed only once in a Chinese family[4]. Of the other hæmoglobin variants, *E* has occasionally been noticed in Chinese. However, this is a rare finding, and the frequency cannot be compared with that observed in the neighbouring Burmese or Siamese, and certain Malayan, Cambodian and Indonesian communities. Hæmoglobins *S*, *C* and *D*, which are present at some frequency in certain non-Mongoloid populations, have so far never been described in Chinese, neither have been the rarer hæmoglobins *I*, *K*, *L*, *M*, *N*, *O* and *P*.

We have examined several thousand Chinese blood samples, about 5,000 in Singapore (F. V.) and about 500 in London (H. L. in collaboration with R. Bhagvan Singh, Medical Research Institute, Kuala Lumpur, and G. L. Robinson, Seamen's Hospital, Greenwich). Among these, two examples of hæmoglobin *J* were seen[5]. We are now able to record the finding of hæmoglobin *G* in a Chinese woman. The observation was made in the course of a survey of bloods from pregnant women sent for Wassermann tests to the Pathology Department, General Hospital, Singapore. The hæmoglobin of patient 'C3565' resolved on paper electrophoresis at alkaline *p*H into two components, one with the mobility of hæmoglobin *A* (65 per cent) and one with that of hæmoglobin *G* (35 per cent). Hæmoglobin *G* moves under these conditions only slightly more slowly than hæmoglobin *Q*, and slightly faster than hæmoglobins *L*, *P* and *D*, but on chromatography at *p*H 6·0 using ion-exchange resin these hæmoglobins are easily distinguished[4].

There was a slight degree of anæmia (12 gm. hæmoglobin per 100 ml. blood), but this was attributed to pregnancy and iron deficiency. After delivery, and following treatment with iron, the anæmia was corrected and the hæmoglobin-level rose to 14 gm. per 100 ml. blood. There were no morphological abnormalities of the erythrocytes, and fœtal hæmoglobin was not found.

The woman became apprehensive when a special interest was shown in her blood. At first a family study was refused, and soon afterwards the whole family moved to an unknown address in Malaya.

Hæmoglobin *G* was first seen in a West African[6], and its genetic and electrophoretic characteristics have been described by Edington, Lehmann and Schneider[7]. Two further instances of hæmoglobin *G* have been seen in American Negro families by Schneider and Haggard[8], and one in a Nigerian family by N. A. Barnicot, E. M. Shooter and J. P. Garlick (personal communication). A hæmoglobin resembling *G* has been described by Schwartz *et al.*[9] in an Italian family. As this hæmoglobin migrated slightly faster than *G* on electrophoresis at alkaline *p*H, it is possible that this was *Q*. A re-examination by resin chromatography should decide this question.

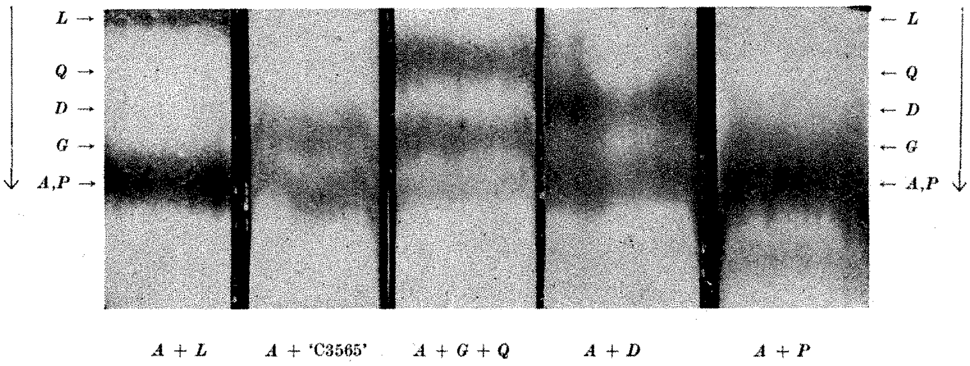

Fig. 1. Separation by resin chromatography on five 'Amberlite *IRC* 50' columns of hæmoglobin *G* from other hæmoglobins showing on paper electrophoresis at *p*H 8·6 only small differences in mobility. The small component in front of the *A* + *P* mixture is a 'pre-*A* band' sometimes seen in samples of hæmoglobin *A* by this technique. For details of technique, see ref. 11. Paper electrophoresis at *p*H 8·6 in order of mobility: *A*, *Q*, *G*, *L* ≡ *P*, *D*. Resin chromatography in order of mobility: *A*, *P* (*P* does not separate from *A*; the mixture forms a broad band), *G*, *D*, *Q*, *L*

Electrophoretic and chromatographic properties depend on the net charges of the globin molecule. Thus hæmoglobins *S* and *D* behave identically on open boundary and paper electrophoresis and in their chromatographic behaviour, but differ in the solubility of the ferrohæmoglobin, and on agar electrophoresis at *p*H 6·0. Hæmoglobins A_2 and *E* have been found to be identical by the current chemical and physical methods of analysis, yet preliminary investigations have demonstrated a difference in their amino-acid sequence (V. M. Ingram, personal communication). The finding of a hæmoglobin variant in this Chinese woman which has the electrophoretic and resin chromatographic properties of hæmoglobin *G* does not necessarily imply its complete identity with the variant seen in West Africans and American Negroes. However, this consideration applies to all identifications of hæmoglobin variants made on the basis of electrophoretic and chromatographic analysis[10].

Comparative Kinetic Behaviour of Thrombin, Plasmin and Trypsin toward Synthetic Substrates

THROMBIN preparations catalyse the hydrolysis of synthetic arginyl[1] and lysyl[2] substrates. While plasmin and trypsin may appear as contaminants in thrombin preparations, we present here kinetic data for the action of these three enzymes toward *p*-toluenesulphonyl-L-arginine methyl ester (I) and the methyl and ethyl esters of lysine which rule out plasmin or trypsin impurities as the origin of the lysyl esterase activity of thrombin.

The kinetic studies were carried out with various thrombin preparations having the following activity towards (I), the substrate adopted for thrombin assays[3]: Seegers citrate-thrombin, 1,000 I units/mgm.; Seegers bio-thrombin, 100 I units/mgm.; Parke, Davis 'Bio-thrombin', 12 I units/mgm. None of these preparations is as pure as that which is attainable (at least 2,000 I units/mgm.) by the procedure of Rasmussen[4]. However, as will be shown, the state of purity does not affect the conclusions.

Experiments on the thrombin – lysine methyl ester reaction were carried out in 0·15 *M* potassium chloride at 25° using 100 I units of thrombin/ml. The hydrolytic reaction was followed by the *p*H-stat method[3] for 30 min. with appropriate corrections for non-enzymatic hydrolysis. The range of concentrations of the lysine methyl ester was limited to 0·001–0·01 *M* since, at higher concentrations, the ionic strength contributed by the dihydrochloride can reduce thrombin activity[3,5,6]. Nevertheless, a significant departure from first-order behaviour in substrate concentration was obtained, thereby permitting a Lineweaver–Burk analysis to be applied to the results.

Various aspects of the kinetic properties of the three enzymes under consideration appear in Table 1; a brief discussion follows.

(*a*) Whereas the plasmin – lysine ethyl ester and trypsin – lysine ethyl ester reactions attain the zero-order region at about 0·03 *M* and 0·02 *M* lysine ethyl ester, respectively, the zero-order region is not reached in the thrombin – lysine methyl ester reaction even at 0·1 *M* lysine methyl ester. Both plasmin and thrombin show zero-order behaviour towards (I) at concentrations of about 0·02 *M*, although the inhibition of plasmin at concentrations of (I) greater than 0·05 *M* (ref. 7) is not observed with thrombin[1,3].

(*b*) The maximum velocity V_m at *p*H 7·0 at 25°, obtained from the Lineweaver–Burk plot, is 0·0036 micromole lysine methyl ester/ml./min. per I unit of thrombin. This may be compared with the value[3] of 0·1 for the thrombin-induced hydrolysis of (I) at *p*H 8·0 at 25°. (By definition[3], 1 unit of thrombin hydrolyses 0·1 micromole of (I)/ml./min. at *p*H 8·0 at 25°.) Although k_3 cannot be computed on an absolute basis because the specific activity of thrombin is unknown, we can compute the ratio of k_3 for I and lysine methyl ester at the same enzyme concentration as the ratio of the values of V_m. This is 28 for thrombin, 1·4 for plasmin and 21 for trypsin.

(*c*) The Lineweaver–Burk plot gives a value of K_m = 0·070 *M* for thrombin on lysine methyl ester at 25°. This is significantly larger than 0·017 *M* for plasmin on lysine ethyl ester[7] at 37°, although a good comparison of K_m values cannot be made because of the difference in temperature. It is of interest to note that K_m for thrombin, plasmin and trypsin toward (I) seems to be identical.

(*d*) Because of differences in buffer ions, it is not possible to base any definite conclusions on differences in the *p*H optima.

Previous results[2] on the absence of STI inhibition of thrombin and the foregoing kinetic considerations indicate that the lysyl esterase activity in thrombin preparations does not arise from the presence of either plasmin or trypsin. Perhaps the strongest

Table 1. KINETIC DATA

Enzyme	Substrate concentration for zero order		Ratio of k_3 for (I) to k_3 for methyl or ethyl lysine ester	K_m		*p*H optimum	
	Lysyl ester	(I)		Lysyl ester	(I)	Lysyl ester	(I)
Thrombin	not reached (> 0·1 *M*)	0·01 *M* (ref. 3)	28	0·070 *M*	0·0043 *M* (ref. 1)	7	8 (ref. 3)
Plasmin	0·03 *M* (ref. 7)	0·015–0·05 *M**	1·4 (ref. 7)	0·017 *M* (ref. 7)	0·004 *M* (ref. 7)	6·5 (ref. 7)	9 (ref. 7)
Trypsin	0·017 *M* (ref. 8)	0·006 *M* (ref. 9)	21 (ref. 7)	—	0·004 *M* (ref. 10)	7·5 (ref. 7)	8 (ref. 9)

* Substrate inhibits at concentrations exceeding 0·05 *M* (ref. 7).

evidence that thrombin is itself a lysyl esterase is the finding that, regardless of the state of purification or type of preparation, the ratio of the activity of (I) to lysine methyl ester or ethyl ester remains constant. Thus, a 100-fold increase in purity resulted in only minor changes in the magnitude and shape of the *p*H – lysine methyl ester activity curve. The same holds true for the *p*H–(I) activity curves for these preparations[3].

In conclusion, thrombin has lysine esterase activity but, as discussed elsewhere[11], the lysine esterase site probably differs from the hydrolytic site for (I) and for fibrinogen. Further studies on thrombin are in progress.

Vanadium Inhibition of Phospholipid Synthesis and Sulphydryl Activity in Rat Liver

THE effect of various transition elements on lipid and sterol metabolism has received attention in recent years[1]. For example, both vanadium and members of the rare-earth group are capable of producing a fatty infiltration of the liver. Furthermore, vanadium can cause a marked reduction in cholesterol and phospholipids[1,2]. In this connexion, work has been directed towards investigating a possible prophylactic action of vanadium against atherosclerosis[2]; it has been suggested that disruption of the endogenous balance of the transition elements in the liver could underlie the pathogenesis of this disease[1].

The increased *in vitro* oxidation of the fatty acid moiety of phospholipids occurring in the presence of vanadium[3] may account for the decreased phospholipid levels in animals fed vanadium, but it has not ruled out the possibility of an independent effect of vanadium in retarding liver phosphatide synthesis. This possibility was tested *in vivo* by measuring the incorporation of phosphorus-32 into liver phospholipids of rats shortly after injection of labelled phosphate.

Since Mountain *et al.*[4] have previously reported interference of sulphur amino-acid metabolism in vanadium toxicity, an additional group of animals was used to ascertain the effect of vanadium on the incorporation of L-methionine-^{35}S into liver protein, and on the amount of sulphydryl soluble in trichloracetic acids in the liver.

The Sprague–Dawley rats weighing approximately 170 gm. used in these studies were maintained on a 5 per cent casein diet[5] for 11 days. Animals were injected intraperitoneally with a vanadyl sulphate solution (0·75 mgm. vanadium in 0·5 ml. saline/100 gm. body-weight)[1] or saline (0·5 ml./100 gm. body-weight). The isotope (10 μc. of $NaH_2{}^{32}PO_4$ or 15 μc. of L-methionine-^{35}S) was administered by the same route immediately after the animals received the vanadium or saline. The rats were killed 3 hr. later. The livers, after being rapidly excised and weighed, were analysed in a manner similar to that described previously for phospholipid[5] and sulphur[6] turn-over. The relative specific activity of the phospholipids and the specific activity of total protein sulphur were calculated from the chemical and radioactive measurements.

Table 1. EFFECT OF VANADIUM ON PHOSPHOLIPID SYNTHESIS AND SULPHUR TURN-OVER IN LIVER OF RATS

	Saline controls	Treated with vanadium
No. of rats	6	6
Phospholipid relative specific activity*	0·101 ± 0·015	0·075 ± 0·018§
Protein sulphur specific activity†	12·8 ± 1·8	16·8 ± 1·0§
Sulphydryl compounds, mgm.‡ (TCA soluble)	0·37 ± 0·05	0·26 ± 0·03§

* Relative specific activity =

$$\frac{\text{specific activity of phospholipid-phosphorus}}{\text{specific activity of inorganic phosphorus}}$$

where the specific activity of phosphorus is defined as

$$\frac{\text{(counts/min. phosphorus-32)}}{\text{(mgm. phosphorus) (counts/min. of dose injected} \times 100)}$$

† Sulphur specific activity =

$$\frac{\text{(counts/min. sulphur-35) dekagm. of body-weight)}}{\text{(mgm. sulphur) (counts/min. of dose injected)}}$$

‡ Reported as mgm. of cystine per gm. of wet weight.

§ $P < 0·05$ calculated from the *t* test of significance. The figures preceded by the ± are the standard deviation.

The results are reported in Table 1. They suggest that the decreased phospholipid values observed in animals fed vanadium[2] result from inhibition of phospholipid synthesis and are probably augmented by oxidative degradation[3]. An alteration in sulphur metabolism is also apparent from the reduction of the sulphydryl content of the liver soluble in acid and from the increased turn over of protein sulphur in the animals which received the vanadium.

Relative Stability of Adrenaline, Noradrenaline and 5-Hydroxytryptamine subjected to Various Simple Treatments

WHEN the distribution of active materials in vertebrate tissue is being studied, it is necessary to free tissue extracts from substances which interfere with the bioassay of 5-hydroxytryptamine. Garven[1] has described a method for the destruction of polyphenols by the polyphenol oxidase present in mushroom juice. The juice contains both polyphenol and monophenol oxidase, and her method therefore makes use of the faster inactivation of adrenaline and noradrenaline by polyphenol oxidase than of 5-hydroxytryptamine by monophenol oxidase. The present method depends on the differential stability of 5-hydroxytryptamine, adrenaline and noradrenaline in alkaline solution.

Table 1. EFFECT OF TEMPERATURE AND *p*H UPON RESPONSE OF RAT STOMACH TO SOLUTIONS CONTAINING 5-HYDROXYTRYPTAMINE (5-HT), ADRENALINE (Ad) AND NORADRENALINE (nor-Ad)

All recoveries as percentage (mean ± standard error) of response to untreated solutions containing 10 or 20 mμgm./ml. 5-hydroxytryptamine base (5-hydroxytryptamine creatinine sulphate, May and Baker)

Figures in brackets show number of separate experiments performed

*p*H	Duration of treatment (min.)		Percentage of response to control sol. (5-HT only, *p*H 6·8–7·8, untreated)			
	Room temp.	98° C.	5-HT	5-HT + Ad 1 μgm./ml.	5-HT + nor-Ad 1 μgm./ml.	5-HT + Ad 1 μgm./ml. + nor-Ad 1 μgm./ml.
6·8–7·8		1	99·3 ± 0·75 (4)	0 (2)	60·5 ± 10·5 (2)	—
		5	97·0 ± 6·00 (2)	—	—	97·0 ± 8·00 (2)
	120–240		100·0 ± 3·30 (15)	Relaxation (6)	Relaxation (6)	Relaxation (2)
9·6		1	97·3 ± 1·50 (4)	93·0 ± 1·00 (2)	91·0 ± 3·00 (2)	—
		2	86·0 (1)	—	—	78·0 (1)
	120		—	—	0 (1)	—
10·8–11·2		1	67·8 ± 2·92 (4)	55·0 ± 5·00 (2)	76·5 ± 7·50 (2)	—
	5		96·5 ± 4·50 (4)	0 (5)	—	—
	30		98·0 ± 2·00 (2)	114·0 ± 2·00 (2)	—	—
	60		96·9 ± 3·78 (7)	101·8 ± 3·11 (6)	—	103·0 (1)
	120		88·2 ± 2·97 (5)	92·5 ± 12·50 (2)	92·3 ± 3·80 (4)	80·0 (1)

Solutions containing 10 or 20 mμgm./ml. 5-hydroxytryptamine were prepared, ± 1 μgm./ml. adrenaline and ± 1 μgm./ml. noradrenaline, in Tyrode's solution bubbled for 30 min. previously with a gas mixture of 5 per cent carbon dioxide, 95 per cent oxygen. The volume (0·2–0·4 ml.) of analytical grade sodium hydroxide to give the required *p*H was added to 25-ml. aliquots of solutions in 50-ml. stoppered flasks or test-tubes. The solutions were well mixed by shaking and either left to stand on the bench at room temperature or heated in a water-bath at 98° C. and then cooled in iced water. Analytical grade hydrochloric acid was added to restore the *p*H to neutral, the solutions were well shaken and remained on the bench at room temperature until they were assayed (about 2 hr. later). There is no significant loss of activity during this time (*P* > 0·2). The *p*H of the solutions was checked initially with Johnsons's narrow range indicator papers and in critical experiments by an E.M.I. direct-reading *p*H meter.

5-Hydroxytryptamine was assayed upon the rat stomach preparation[2] in Tyrode's solution at 38° C. Doses were given according to a 'Latin square' design. In all experiments the test solutions were compared with untreated solutions of 5-hydroxytryptamine to which Tyrode's saline had been added in volumes equal to those of sodium hydroxide and hydrochloric acid. All recoveries are expressed as percentage of response to untreated solutions containing 5-hydroxytryptamine only.

Table 1 summarizes the results of fifteen experiments. Adrenaline and noradrenaline in concentrations 50–200 times those which were found to abolish the response of the tissue to the stated amounts of 5-hydroxytryptamine are completely inactivated by standing for 30–60 min. at *p*H 11 without loss of 5-hydroxytryptamine itself. Heating to 98° C. for 5 min. at *p*H 7·8 is equally effective. Heating for 1 min. at 98° C. and *p*H 9·6 leads to a small loss, and at *p*H 11 to a considerable loss of 5-hydroxytryptamine activity. This last result differs from that reported by Pernow[3].

Human serum to which adrenaline, noradrenaline and 5-hydroxytryptamine had been added was extracted by addition of four volumes of acetone[4]. When sodium hydroxide was added to the extracts to give a *p*H of 10·5–11·0 for 30–60 min., adrenaline and noradrenaline were destroyed whereas 5-hydroxytryptamine was unaffected. Three such experiments gave recoveries of 5-hydroxytryptamine between 92 and 100 per cent of the control value (96·2 ± 1·7).

Thus both adrenaline and noradrenaline in a concentration of 50–200 times that of 5-hydroxytryptamine—a ratio which occurs in certain parts of the brain of vertebrates[5,6]—are selectively destroyed by treatments which have little or no effect on the concentration of 5-hydroxytryptamine.

Application of Direct Photographic Photometry to Preparative Electrophoresis

THE supporting medium of most preparative methods of electrophoresis includes a solidified gel or porous solid in order to reduce thermal convection[1]. A buffer stabilized in the form of a clear solution, without a solid support, would have the advantages of avoiding adsorption effects between the migrating molecule and the solid, and would make it possible to follow the migrating substances by direct photometric procedures[2]. A method of electrophoresis has been described which uses, as a medium, a thin film of buffer solution[3]. Thermal convection can be effectively controlled by dissolving in the buffer a sufficient quantity of gelling agent to impart a trace of rigidity or thixotropy. Not enough is added to cause a loss of fluid characteristics (that is, to run freely when tilted) or a loss of transparency. The amount of protein that can be separated can be increased for preparative purposes by increasing the thickness of the buffer from that of a thin film to a solution 1 cm. or more. Direct photographic photometry applied to the separation and isolation of serum proteins by this method was accomplished by the following procedure.

A cell bottom 6·5 in. × 13 in. was constructed of two 6·5 in. squares of Corning No. 7910 glass. These were glued together with glass strips to form a rectangular container. 'Difco' agar, one of various gelling agents which can stabilize in trace amounts, was added to a 0·02 *M* veronal buffer, *p*H 8·6, to a concentration of 0·16 gm. per cent. It was dissolved by boiling, and 500 ml. of the solution was poured into the cell while still warm. Cellulose sponges were used for electrical contact with electrode vessels, each filled with the same solution up to the same level as in the cell. The solution was permitted to stand for a half-hour, and a potential gradient of 6·1 V./cm. was then applied. 1 hr. later the serum was introduced by attaching a 14 cm. × 0·6 cm. piece of Whatman No. 17 paper with thread to a plastic frame, wetting the paper with serum, and then inserting the frame down into the buffer solution along vertical grooves which had been prepared inside the glass sides. Serum can also be applied by solidifying a block with agar.

The proteins were followed at various times during the course of their migration by inserting photographic plates into a space left vacant under the cell. These were exposed to light of 283 mμ wave-length for 11 min. A Beckman *D.U.* monochromator with a hydrogen lamp was used as light source. The monochromatic light beam was extended horizontally for 18 ft., then deflected by means of an aluminium mirror down through the electrophoretic cell. The photographic plates were developed, and the positions of the protein components were determined by means of a centimetre scale drawn on the bottom of the cell (Fig. 1). The current was then disconnected, and the protein fractions were separated by inserting aluminium sheet dividers down into the solution at appropriate positions along the centimetre scale. The dividers were connected by tape along the outside of the cell, which was placed in a freezer. The frozen sections were removed individually, thawed, and the agar removed by centrifugation. After concentration to approximately the original volume, each fraction was subjected to electrophoresis, along with the original serum, by the fluid film technique. The results, after staining with amido black, are presented in Fig. 2. Densitometer curves were obtained from the stained electropherogram and from the third photographic plate of Fig. 1.

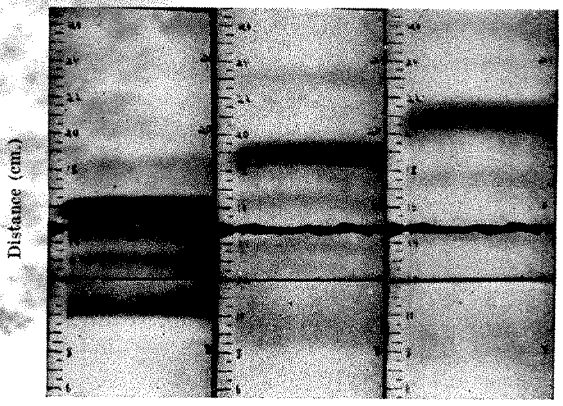

Fig. 1. Printed photographic plates obtained at 2·5, 4·5 and 5·5 hr. of migration. The line at 12 cm. was due to the frame used to apply serum, and the irregular line at 14·7 cm. was caused by the glue connecting the two silica plates of the cell bottom

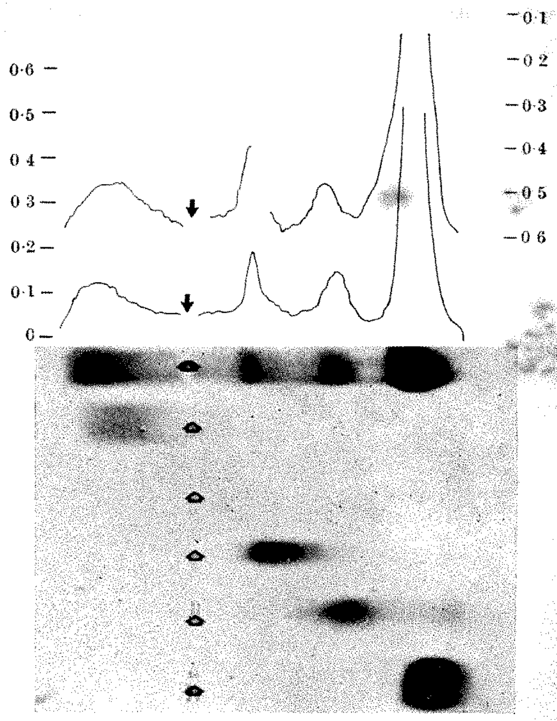

Fig. 2. Film electrophoresis of the original serum and components included in the following sections of the preparative cell: 6–10, 10–13, 13–16, 16–19 and 19–22 cm. The top curve gives the absorbancy along the last photographic plate of Fig. 1, right-hand scale, while the lower curve represents the stained pattern below it, left-hand scale. Arrows indicate position of application

Although the volume of serum applied above was only slightly more than 1 ml., considerably larger amounts can be used. The ability to follow the course of the proteins during electrophoresis and to isolate the individual components by the simple method described, without continuous sectioning or analysis along the migration path, may prove of value for various purposes. The use of ultra-violet photographic photometry for quantitative measurements is being investigated.

Co-ordination in Thorium-IV Acetylacetonate

Although the number of atomic species with co-ordination number eight is not large, little is known about the structure of eight-co-ordinated complexes. Up to now only two of five possible polyhedra have been established for this co-ordination, namely, a trigonal dodecahedron and an Archimedean square antiprism[1], while cube, triangular face-centred and rectangular face-centred trigonal prisms have not yet been observed. These polyhedra were proposed on the basis of quantum-mechanical calculations on the form of hybrid bond orbitals.

In general, it is possible to predict the co-ordination polyhedron for a given complex if the valency electron orbitals are known and if the co-ordination is not high. This is not the case with heavy atoms, particularly with actinides, where there are many electrons distributed over *s*, *p*, *d* or *f* orbitals, so that we cannot recognize which is the most favourable configuration for covalent bonding[2]. The direct experimental verification, for example, the X-ray analysis of the crystal structure of heavy metal complexes, is therefore of considerable interest in inorganic stereochemistry.

Metal acetylacetonates of formula $M^{IV}(C_5H_7O_2)_4$, where M^{IV} is zirconium, hafnium, thorium, uranium, polonium or cerium with the co-ordination number eight, are a very promising subject for such analysis. We started our work with the thorium compound[3].

The crystals of thorium acetylacetonate are monoclinic holohedral, the space group being $C_{2h}^5 - P2_1/c$ with four molecules in the unit cell which has the dimensions: $a = 11 \cdot 67$ A.; $b = 12 \cdot 69$ A.; $c = 16 \cdot 95$ A.; $\beta = 112° \, 15'$.

Multiple-film Weissenberg photographs, taken with copper $K\alpha$ radiation, were used to obtain intensity data for $h0l$ and $0kl$ reflexions. The relative intensities were determined from the optical densities measured at the centre of each spot by means of a microdensitometer. In order to facilitate the absorption correction the specimen was made cylindrical by grinding. The thorium atom parameters were obtained from [010] and [100] Patterson projections. The signs of the structure factors $F(h0l)$ and $F(0kl)$ were determined using only thorium atom contributions and then the corresponding projections of electron density distribution were computed by the Fourier synthesis. Besides thorium atom maxima at $x = 0 \cdot 191$; $y = 0 \cdot 146$; $z = 0 \cdot 200$, a large number of peaks appeared in both projections. A careful examination of the [010] projection revealed a six-membered ring containing the thorium atom peak as well as both methyl-group peaks. It belonged to the acetylacetonate ring which was nearly parallel to the plane of projection. Next, a trial procedure was undertaken which consisted mainly of casting the shadow of wire and sphere models on both electron density maps by means of a distant source of parallel light. At first the square antiprism as a co-ordination polyhedron was assumed, since it involved only three considerably different geometrical isomers (Fig. 1) with the symmetry D_4, D_2 and C_2, respectively. This first step was fruitful and all peaks on both projections were explained by the structure based on the configuration (*b*) in Fig. 1.

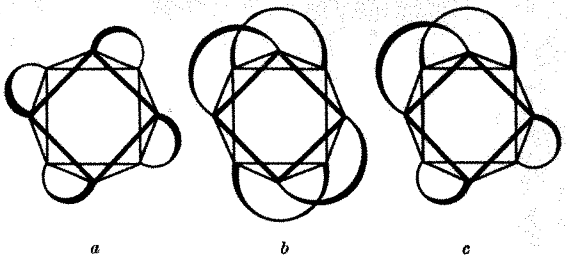

Fig. 1. Geometrical isomers of an eight co-ordinated acetylacetone complex in the Archimedean square antiprism form

The model of the thorium acetylacetonate molecule related to both projections is shown in Fig. 2. Besides the diffraction effect caused by the heavy thorium atom, the maxima in the projections overlapped in many places, which interfered with an exact evaluation of atomic positions. The structure is now being refined so that the present results are only preliminary.

The bond-length Th—O is $2 \cdot 41$ A., and the OThO bond angle is 70°. The O . . . O distance within an acetylacetonate ring amounts to $2 \cdot 74$ A. and the distances between two adjacent rings are $3 \cdot 05$ A. and $3 \cdot 10$ A., along the edge of square and triangular faces, respectively. It follows, therefore, that the actual co-ordination polyhedron is a square antiprism with a slight characteristic distortion. An idea of the amount of distortion can be obtained if we take the Th—O bond length for granted, when the ideal square antiprism requires an edge of $2 \cdot 93$ A., a distance of

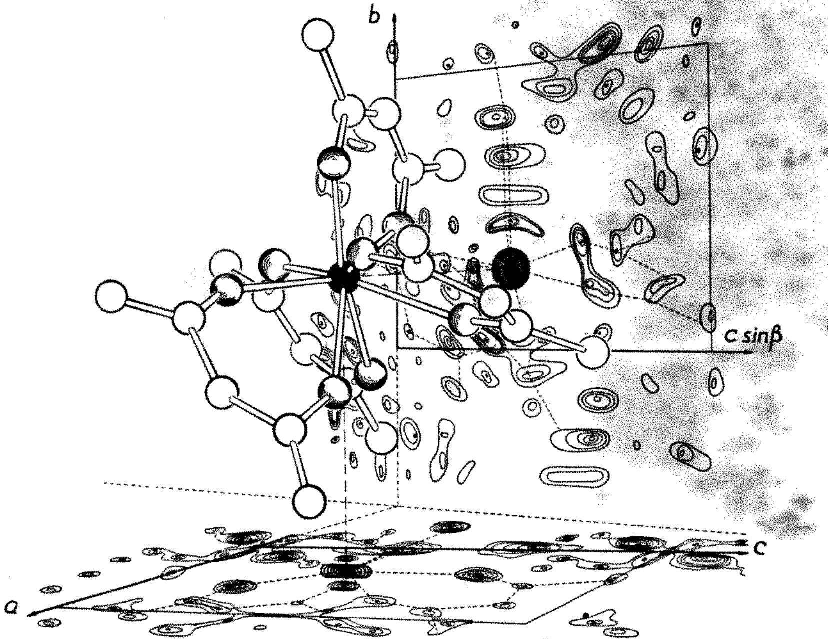

Fig. 2. Perspective view of the model of thorium-IV acetylacetonate molecule as obtained from ($h0l$) and ($0kl$) electron-density maps

2·47 A. between square faces (observed value 2·53 A.) and a bond angle of 75°.

Further analysis of the structure is now in progress and the results will be published in detail elsewhere.

Absorbents for Aldehydes and Olefins

The usual forms of absorbents for aldehydes, such as ammonia and bisulphite solutions, cannot readily be used in vacuum systems because they are liquid and volatile. A very convenient absorbent may be made by suspending on 25–52 mesh powdered firebrick ('Fossalsil') 25 per cent by weight of a mull of sodium bisulphite in ethylene glycol. We have repeatedly used this powder packed in 10 cm. of a 15 mm. internal diameter tube to absorb the butyraldehyde remaining in a mixture after a photolysis. Subsequent analysis of the reaction products indicates that less than 0·3 μmole out of the initial 500 μmoles remains unabsorbed after the vapour has been passed three times through the packed tube. Acetone is not similarly absorbed.

An excellent absorbent for olefins may similarly be made from a mixture of 9 gm. mercuric acetate, 3 gm. mercuric nitrate and 20 gm. ethylene glycol on 100 gm. of firebrick.

This research was supported by a grant from the Petroleum Research Fund administered by the American Chemical Society. Grateful acknowledgment is made to the donors.

Formation of a Transition Metal–Hydrogen Bond in Aqueous Solution

There are several known transitional metal complex systems which are concerned with either the absorption or evolution of molecular hydrogen, and some of them, for example the copper acetate in quinoline system, can function as hydrogen-transfer systems[1–3]. It has been suggested by many workers in the past that complexes containing hydrogen bonded to a transitional metal are involved in these systems, but direct proof for the existence of such bonds has been lacking.

A sufficient number of complex compounds containing metal-hydrogen bonds has now been studied by high-resolution nuclear magnetic resonance methods to permit the specific characterization by this technique of a proton bound to a transitional metal. Thus the compounds $(C_5H_5)_2ReH$, $(C_5H_5)_2ReH_2^+$ (ref. 4), $HCo(CO)_4$ (ref. 5), $H_2Fe(CO)_4$ (ref. 6), $HMn(CO)_4$ (ref. 7), $H\mathit{M}(CO)_3(C_5H_5)$ [M = Cr, Mo, W] (ref. 8), $HPtCl(PR_3)_2$ (ref. 9), and $(C_5H_5)_2\mathit{M}H_2$ [M = Mo, W] (ref. 7) have all been shown to have proton resonances shifted to 450–800 cycles/sec. (at 40 Mc./s.) relative to water, on the high field side.

During the course of studies of such compounds and related systems we have examined the cobaltous cyanide–potassium cyanide system, which has been rather carefully studied by Winfield and others[1 2 10]. In aqueous solutions a proton resonance at a position characteristic for a proton bound to the metal atom has been detected, at 698 ± 2 cycles/sec. (at 40 Mc./s.) relative to water. The resonance is not observed at cyanide/cobalt ratios less than 3·5, and it is not affected by excess cyanide up to a cyanide/cobalt ratio of 8·0. The presence of an atmosphere of hydrogen above the solution is not necessary for the appearance of this resonance line, so that the proton bound to the metal is clearly derived from water. The rest of the water molecule, either as free OH radicals or as oxygen, presumably oxidizes the aquo cobaltous cyanide complex. The proton resonance disappears on admission of oxygen and other oxidizing agents to the solution. While there is, as yet, no specific information concerning the nature of the hydrogenated species, it seems reasonable to postulate that it is the $[HCo(CN)_4]^=$ ion. The large chemical shift of the proton resonance shows that the proton in such a species is exchanging with water in the aqueous alkaline solution only very slowly, and the average chemical life-time of the proton on the metal atom must be greater than about 10^{-4} sec.

These studies will be more fully described elsewhere.

A Radiocarbon Profile in the Tasman Sea

During recent hydrological investigations in the eastern Tasman Sea by the New Zealand Oceanographic Institute a series of sea-water samples was collected for carbon-14 analysis as mentioned recently by Rafter and Fergusson[1].

The sampling position (New Zealand Oceanographic Institute Station *A*344) was in approximately latitude 37° 25′ S.; longitude 170° 35′ E. over

Table 1

Depth (metres)	Volume carbon dioxide (litres)	^{14}C activity w.r.t. *Pinus* (per cent)	'Age' (before present) (years)
0	12·4	+1·01 ± 0·50	0
100	15·0	−0·2 ± 0·45	100 ± 50
280	18·0	−6·4 ± 0·35	590 ± 50
830	17·4	−8·0 ± 0·38	720 ± 50
1,400	21·0	−16·1 ± 0·40	1,480 ± 60

the head of the New Caledonia Trough in a depth of some 1,900 m. The station was worked on February 14, 1957, under the direction of Dr. R. W. Burling from R.N.Z.F.A. *Tui*. 40 gallon samples were obtained, using an open-ended sampler with a capacity of 20 gallons. Sample depths, the carbon-14 activity of samples with respect to that of the softwood *Pinus radiata*, the New Zealand contemporary standard, together with the derived apparent ages (namely, the time elapsed since air-sea equilibrium obtained), are given in Table 1. These analyses were made in the Nuclear Sciences Division of the Department of Scientific and Industrial Research, Lower Hutt, under the direction of Mr. T. A. Rafter.

The hydrological situation is described in terms of the results of a standard reversing bottle cast made at this station (Table 2). Water analyses and reduction of the results were by me.

Table 2

Depth (metres)	Temperature (°C.)	Salinity (‰)	Dissolved oxygen (ml./l.)
0	21·15	35·45	4·82
10	21·14	35·46	5·10
20	21·11	35·46	5·54
30	21·00	35·45	6·45
50	19·86	35·44	7·18
75	16·94	35·45	5·77
100	16·10	35·46	5·08
150	14·90	35·46	3·82
200	14·09	35·43	2·50
300	12·61	35·26	1·00
400	11·10	35·11	0·87
500	9·76	34·99	1·01
600	8·70	34·90	1·29
800	6·88	34·76	1·88
1,000	5·47	34·66	2·51
1,200	4·39	34·64	3·18
1,500	3·36	34·71	3·80
1,800	2·71	34·79	4·29

The observations have been plotted in the form of temperature, dissolved oxygen and 'age' as functions of salinity (Fig. 1). By projecting the tangents on the temperature–salinity curve, the three primary water types giving rise to the observed characteristics (assuming predominant vertical mixing) have been derived. *A* is the upper subtropical water at a depth of about 160 m., water above this depth being subject in large measure to external (climatic) influence. *B* is the core of the Antarctic intermediate water at about 1,100 m. (originating in surface layers near the Antarctic Convergence) and *C* the deep water (probably entering the Pacific from the Atlantic via the India Ocean) which here extends to the bottom. A discussion of the history of these water masses forms the basis of a consideration (in preparation) of the full hydrological results of the cruise from which the results given here were derived. Particularly noteworthy are the absence of circumpolar bottom water (probably due to isolation by bottom topography) and the significant increase in salinity of the deep water over that found by earlier investigations (for example, *Dana* station 3650 (1920)) in this area. This increase has been traced over a large area of the south-west Pacific.

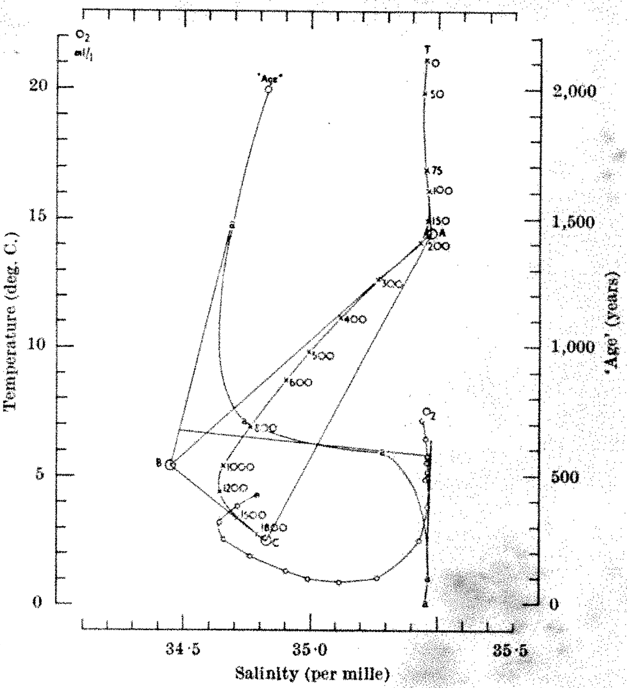

Fig. 1. For station *A*344 the temperature (*T*, ×———×), dissolved oxygen content (O_2, ○———○) and carbon-14 'age' (*a*———*a*) are plotted as functions of salinity in the water column over the New Caledonia Trough in the eastern Tasman Sea on February 14, 1957. *ABC* is the triangle of mixing derived from the temperature–salinity correlation, beside which is entered a depth scale (small figures) in metres

If the carbon-14 activity can be regarded as a conservative water property, the mixing diagram constructed from the 'age'-salinity correlation should indicate a similar water-mass structure to that implied by the temperature–salinity curve. From a graphical construction based on the observations in Fig. 1 it is found that the measured 'ages' are consistent with the temperature–salinity diagram if 'age' values for the primary masses are as follows: *A*, 600 years, *B*, 600 years and *C*, 2,000 years. The prolonged isolation of the deep water (*C*) is notable and may be compared with the value of 2,540 ± 100 years reported by Brodie and Burling[2] from a depth of 2,643 m. in the Southern Ocean south of New Zealand in December 1956. It is likely that the point *C* in Fig. 1 lies above the core properties of deep water because of the relatively shallow depth.

This elementary approach towards accounting for the variation in the carbon-14 activity of the water column in terms of vertical mixing between the main oceanic water masses will need closer examination. Also, because of the time taken to obtain a sufficient volume of water for each determination, only a few points in the vertical profile are sampled. It will be important to see that future samples are adequately located with respect to the turning points in the salinity–depth relationship.

It will be interesting to follow the variation of the 'primary' values derived in the above manner at various points along the cores of the principal water masses, particularly the Antarctic intermediate layer. With the magnitude of lateral mixing defined from temperature–salinity data, it should be possible to make a direct estimate of the velocities involved.

It is noted that the 'age' and distribution of dissolved oxygen in Fig. 1 are of different character, indicating that the concentration of oxygen at depth is here a function of (presumably) biological activity rather than an index of the time since free exchange between air and sea was possible.

Vaporization of Projectiles on Impact

DR. K. H. LIH, director of this Institute, has directed my attention to the article of Dr. F. P. Bowden and Mr. J. H. Brunton about the damage to solids by liquid impact[1]. It would be interesting to know if these authors have noticed the effect of 'explosion' of the water particles when they hit a hard surface at high speeds, similar to that which we observed when making experiments with different metal liners used in so-called 'hollow' or 'shaped' explosive charges; although, of course, the velocities of the liner particles far exceed those which Bowden and Brunton used for propelling their water drops. In the *Scientific Monthly* of February 1951, p. 79, it was remarked that: "Ballistic experiments have shown that particles, travelling at velocities about 4,250 ft./sec., *explode into vapour* on striking the target".

That this is actually so is proved by Fig. 1, which shows the surface of the second steel block (diameter 4 in., height 4 in.) hit by the jet particles which had already passed through the first block of the same dimensions; the vapour of the exploding metal particles condensed on the cold surface and left a white spot around the point of impact. That such spots are not produced by droplets of molten metal forced between the two blocks, but by the condensed vapour, was proved by the following experiment: a brass liner was fired into a steel block provided with several apertures running perpendicular to the jet passage; when the block was cut lengthwise it was discovered that at some places in these holes zinc vapour had condensed, which could only happen if at least part of the metal was in gaseous state.

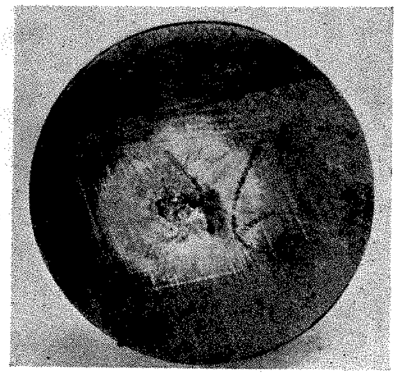

Fig. 1. Condensed metal vapours of exploding jet particles imprinted on the surface of the second steel block

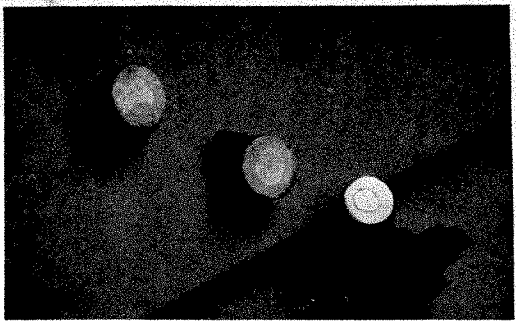

Fig. 2. Cross-sections of 'slugs' showing the copper cores

Fig. 2 explains the formation of the 'slug': small additional copper cones were fixed into the steel liners; the charges were fired horizontally into a sand box, and the metal fragments recovered. The 'slugs' were found to be solid steel bodies with a copper core, which proves that, contrary to some theories, the liners are not turned 'inside out'—at any event at the top—but simply compressed by the force of detonation and torn from the rest of the liners, the lower parts giving most of the high-velocity fragments which penetrate deeply.

Effect of Solar Flares on Earth Satellite 1957β

FIG. 1 appears to demonstrate a correlation between the fluctuations in the rate of decrease of the period of satellite 1957β and contemporaneous variations in total intensity of solar flares.

The upper part of Fig. 1 is a block diagram with ordinates computed from the daily sum, over all observed flares, of their (area × duration). To aid comparison, I have plotted only the arithmetic mean of this sum over periods between successive satellite observations. The scale is shown by the arrow, which denotes the ordinate equivalent to 1,000 sq. deg. min./day (for example, 1 hr.-long class 3 flare per day). The data have been compiled from the Fraunhofer and Meudon daily Sun disks, and I am indebted to Mr. J. H. Reid, of the Royal Observatory, Edinburgh, for this information. For simplicity only flares of class 2 and above were included in the calculations.

The orbital data of the lower part of the figure were prepared from a graph of various observations published by the Royal Aircraft Establishment, Farnborough, for which I am indebted to Mr. D. G. King-Hele. The ordinates denote the difference between the observed rate of decrease of period and a theoretical figure for this quantity (relating to the same stage of the life-time). Because the theoretical rate varies monotonically with time, its introduction in no way obscures the fluctuations of the observed rate, but rather serves to facilitate their presentation. Similarly, the derivation of the theoretical figures used is immaterial in the context.

The similarity of the two sets of fluctuations, even in some small details, is suggestive. If it is conceded that it may not be purely coincidental, it would be

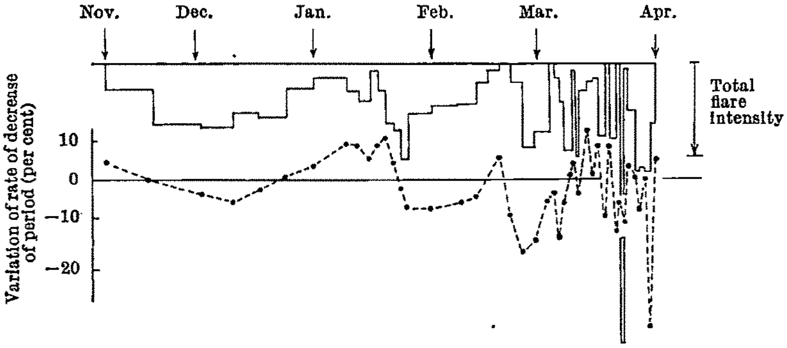

Fig. 1

valuable to establish a possible mechanism for the dependence.

However, it is to be noted that the sense of the relation is such that flares would have to be associated with a temporary decrease in air density, and/or temperature, within the lower ionosphere. (The satellite perigee fell from 140 to 100 miles height during the time shown.) To account for the diagram, this reduction would seemingly have to happen on a world-wide scale, as the perigee ranged during the life-time from middle to equatorial latitudes, and through daylight and night zones.

Reversals of the Earth's Magnetic Field

Among the many surprising results of studies of the natural remanent magnetization of rocks[1], one of the most curious has been the conclusion that the Earth's magnetic field has undergone changes of polarity; that, in fact, reversals of the main field have been a persistent feature of its behaviour. Normal and reversed fields could equally well exist, according to the dynamo theory of the Earth's magnetism[2], but it is not known whether a means of transfer from one field to the other exists.

Several years ago, E. C. Bullard[3] examined the behaviour of a simple homopolar disk dynamo in some detail, and suggested that systems of such dynamos, together with electrical loads, might provide useful analogies to homogeneous fluid dynamos. He found an interesting oscillatory behaviour of the current and angular velocity for a single dynamo, but there was no phenomenon of reversal. Recently, T. Rikitake[4] set out the equations for two disk dynamos coupled to one another, and from a numerical integration concluded that it was possible for the currents in their coils to change sign; in other words, the fields produced could show reversals, at least initially.

Using the digital computer EDSAC II at the University of Cambridge Mathematical Laboratory, I have been able to carry out much more extended numerical integrations of these equations for a range of parameters and initial conditions. These have exhibited some very subtle types of behaviour, and show that reversals can occur under a wide range of conditions. The system has two states of equilibrium, with the currents for one the reverse of the currents for the other. The equilibrium is stable for small oscillations, but for larger departures from the steady-state values many of the solutions oscillate first about one point of equilibrium and then about the other. Fig. 1 shows a striking example of this behaviour; the current in the coil of one dynamo only is given. It oscillates in one manner for some time, reverses for a single oscillation, and reverts to the original manner; then later a whole series of the reverse oscillations takes place. The current in the other coil behaves very similarly in this case, but I have found cases in which one current oscillates, changing sign, whereas the other never changes sign.

The significance of these results lies largely in the fact that the phenomenon of reversal can occur, both in the sense of a change of polarity and in the sense of a true reversal of behaviour corresponding to a change from oscillations about one state of equilibrium to those about another. In a similar way, reversals of the terrestrial field may be occasional phenomena in the course of continual oscillations of considerable amplitude. There is some evidence that the field intensity has decreased in the past 2,000 years[5]. Such changes would affect radiocarbon dating[6], and C. Crowe (see following communication) has found that errors in such dates over the past 3,000 years might well be consistent with an increase and then a decrease of the Earth's field. Thus, oscillations of the main field with a period of some thousands of years, with reversals at intervals of hundreds of thousands of years, would be quite conceivable.

There is no guarantee that the homogeneous dynamo believed to exist in the Earth's core will behave similarly to two coupled dynamos. I hope to examine some more elaborate models which may be more closely analogous to the former, but it would be unwise to press the analogy too far. For example, two dynamos of a scale appropriate to the core would have periods measured in years rather than thousands of years; Bullard[3] has suggested that this is because the system includes nothing equivalent

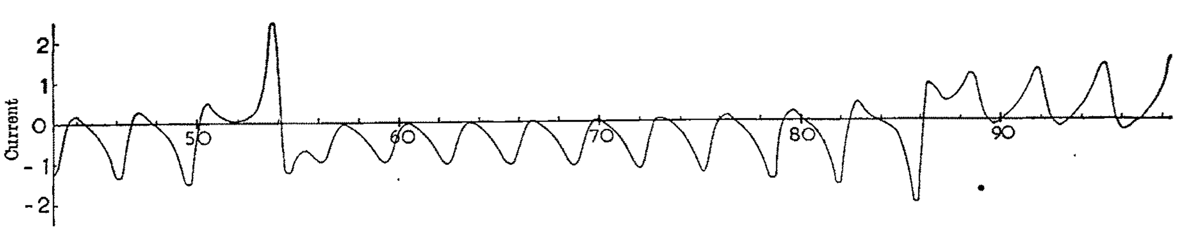

Fig. 1. Current in one dynamo vs. time (in units scaled to become dimensionless). The equilibrium values of the current are ±0·5

to a Coriolis force. (The periods of days observed in some magnetic stars[7] might, however, be reproduced by this model.) Nevertheless, the fact that large-scale oscillations in this simple system can lead to reversals is surely an indication that the origin of reversals of the Earth's main field, and the nature of its variation with time, "though puzzling questions, are not beyond all conjecture".

I wish to thank the National Research Council of Canada for a fellowship supporting this research, and the University of Cambridge Mathematical Laboratory for use of EDSAC II.

Carbon-14 Activity during the past 5,000 Years

VARIATIONS during the past 5,000 years of the concentration of carbon-14 in living material have been investigated with the aid of available radiocarbon dating measurements made with samples which have died at known times.

If the difference, Δt, between the actual age t and the radiocarbon age t' of a specimen is attributed to an initial activity not the same as that of present living material, the change in activity relative to that of the present is given by:

$$R \doteqdot \lambda \Delta t \quad (\lambda \Delta t \ll 1)$$

where $\Delta t = t - t'$ and $\lambda = 1 \cdot 24 \times 10^{-4}$ year^{-1}.

This ratio has been calculated in cases where both a radiocarbon and a reasonably accurate historical or archæological date are available[1]. First, account must be taken of systematic errors in t', chiefly of the use by most radiocarbon dating laboratories of different standards of present activity. This has been attempted by comparing the ages obtained in cases where laboratories have dated the same sample or different portions of a specimen. The scheme adopted, which correlates the results from the various laboratories with those obtained at Groningen, is shown in Table 1. Change in activity (R) *versus* time is shown in Fig. 1.

The activity appears to have followed a cycle with a maximum change of about 10 per cent in the past 5,000 years, taking into account some recent results[2,3]. There is evidence of a sharp peak of about 10 per cent approximately 2,000 years ago. The rapid decrease in the past 100 years or so has been attributed to the 'Suess' effect of dilution of the atmospheric reservoir of carbon-14 due to combustion of fossil fuel[4].

Table 1. SCHEME CORRELATING RESULTS FROM OTHER LABORATORIES WITH THOSE FROM THE UNIVERSITY OF GRONINGEN

	Years to be added to or subtracted from all dates
University of Heidelberg	−375
University of Chicago	0
Institute of Archæology	0
Lamont Geological Observatory	+400
University of Michigan	+400
Swedish Geological Survey	+525

The estimated error of ±100 years in these corrections is not included in the activity error.

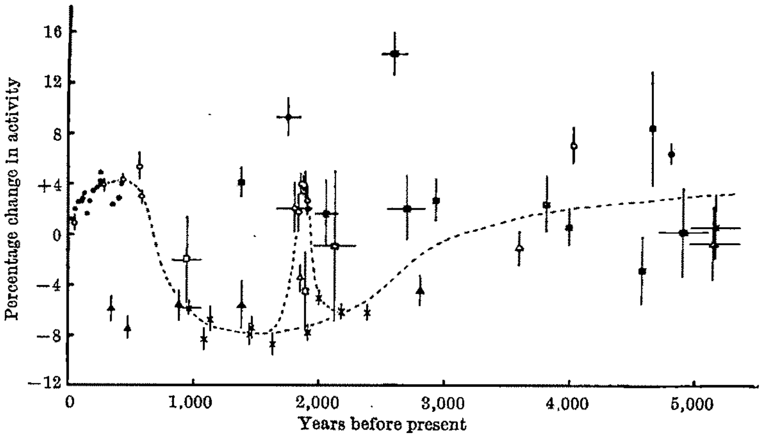

Fig. 1. Change in activity relative to that of the present *versus* time. ■, Chicago; ●, Groningen; ○, Heidelberg; △, Inst. of Arch.; ▲, Lamont; □, Michigan; ×, Stockholm; --- proposed trend. Error in time is ±100 years or less where not shown. The Groningen and Heidelberg results in the past 500 years are obtained from refs. 2 and 3

Regional differences in activity greater than 1 per cent are precluded by the treatment of data in this paper. Evidence for differences of less than about 1 per cent during the past few centuries has been given[2].

Errors in radiocarbon dates of the magnitudes found may be produced by the variations in the intensity of the Earth's magnetic field which have been indicated by measurements of the remanent magnetism of Roman bricks[5]. A cyclical variation in intensity corresponding to that of the activity would not conflict with a dynamo theory of the origin of the Earth's field (Allan, D. W., preceding communication), or with previous work on variations over a long period of the Earth's magnetic dipole[6]. It has been suggested that some activity changes may be due to variations in vertical mixing in the oceans[2]. A recent analysis of the 'Craig' carbon-14 reservoir model[3] indicates that a change of about 10 per cent in the activity would be caused by a change of approximately 100 per cent in the rate of production of carbon-14. Changes of several hundred per cent have been observed in the intensities of the secondary cosmic-ray neutrons[7] and other components[8] following large solar flares, and the effect of such events, though years apart, may be significant.

Changes in activity may be due to combinations of these effects. A recent communication[9] suggests a method of separating the effect of variation in the intensity of the magnetic field from the others. It is hoped that the above results will provide some information for further work.

Thanks for their advice are due to Mr. R. M. Cook, reader in classical archæology, and members of the Department of Archæology and Anthropology, the Sub-Department of Quaternary Research, and this

Department. Assistance in the form of a scholarship from the Royal Commission for the Exhibition of 1851 is gratefully acknowledged.

Infra-Red Transmission Limits and Reflectivity of Lithium-6 Fluoride and Lithium-7 Fluoride

The Industrial Group of the United Kingdom Atomic Energy Authority has made small quantities of lithium compounds, containing different proportions of the isotopes ^{6}Li and ^{7}Li, available to its Research and Development Laboratories at Capenhurst. The material is being used to determine how altering the isotopic ratio ^{6}Li/^{7}Li in lithium compounds affects certain physical properties of these compounds.

Some of the material has been converted to lithium fluoride from which single crystals have been grown in the Natural Philosophy Department, Aberdeen. In the past nine months, several dozen single crystals of lithium fluoride containing different amounts of the isotopes lithium-6 and lithium-7 have been grown there.

Most of the specimens have been slender rods for thermal conductivity measurements, but plates from 1-in. diameter crystals have recently been tested in the infra-red. The results illustrate the effect of a variation in the reduced mass $\overline{M}$ on the infra-red dispersion frequency ω_0. In the notation used by Born and Huang[1],

$$\frac{K}{\overline{M}} = \omega_0{}^2 \left\{\frac{\varepsilon_0 + 2}{\varepsilon_\infty + 2}\right\}$$

Hence, if the force coefficient K and the dielectric constants ε_0, ε_∞ are unchanged by the isotopic substitution, then $\overline{M}\omega_0{}^2$ is constant and $\omega_0 \propto (\overline{M})^{-\frac{1}{2}}$. The reduced masses for ^{6}LiF and ^{7}LiF are 4·570 and 5·125, respectively, and so the infra-red dispersion frequencies ω_0 should be in the ratio $\frac{\omega_0(6)}{\omega_0(7)} = 1{\cdot}059$.

A crystal containing 90 per cent of ^{6}LiF was compared with another containing 95 per cent of ^{7}LiF. Here a frequency ratio 1·051 : 1 is obtained by linear interpolation. Reflectivity data for the short-wave end of the rest-strahlen band is shown in Fig. 1. A Hilger double-beam spectrometer with a potassium bromide prism was used, and the radiation was incident at 20° to the normal on a polished (100) surface. Tests for scattered light were made with barium fluoride and cadmium fluoride filter plates. At wave numbers below 450 cm.$^{-1}$ a considerable correction was required, but above 500 cm.$^{-1}$ the effect was small. The data were scaled by direct substitution of a heavily aluminized optical flat for which 97 per cent reflectivity was assumed.

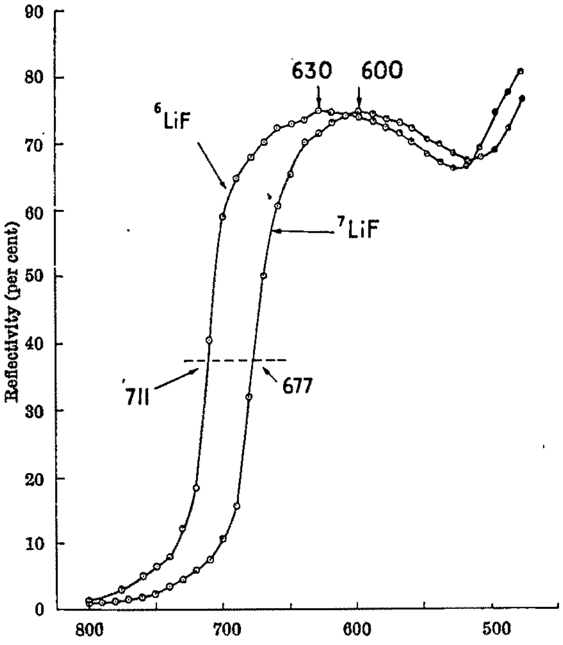

Fig. 1. Variation of reflectivity with wave number

The lithium fluoride band has a subsidiary shortwave peak as described by Hohls[2]. This peak occurs at 630 cm.$^{-1}$ for the ^{6}LiF-rich crystal, and at 600 cm.$^{-1}$ for the ^{7}LiF-rich crystal, giving the expected frequency ratio 1·05 : 1. For both specimens the reflectivity at the subsidiary peak was 75 per cent. A further test can be made in the steeply rising section of the curve by comparing the wave-numbers at which reflectivity reaches 37·5 per cent, that is, one-half of the subsidiary peak value. This occurs at 711 cm.$^{-1}$ for the ^{6}LiF-rich crystal and at 677 cm.$^{-1}$ for the other. The ratio is again 1·05 : 1.

Assuming that the sudden rise in reflectivity occurs in the neighbourhood of the longitudinal lattice frequency ω_L, then ω_0 can be derived from:

$$\omega_0{}^2 = \left\{\frac{\varepsilon_\infty}{\varepsilon_0}\right\} \omega_L{}^2$$

Since for lithium fluoride $\varepsilon_0 = 9{\cdot}27$ and $\varepsilon_\infty = 1{\cdot}92$ the wave number equivalent to ω_0 should somewhat exceed 324 m.$^{-1}$ for pure ^{6}LiF and be somewhat less than 308 cm.$^{-1}$ for pure ^{7}LiF.

The useful transmission limit of an alkali halide crystal also varies in proportion to the rest-strahlen frequency. Fig. 2 shows the absorption coefficient k in cm.$^{-1}$ for the two concentrations. The ^{6}LiF-rich crystal reaches an absorption $k = 1$ cm.$^{-1}$ at a wave number 1,634 cm.$^{-1}$ and the ^{7}LiF at 1,542 cm.$^{-1}$. Here the ratio is 1·059 : 1.

The ^{6}LiF crystal was spectroscopically pure. The main impurities in the ^{7}LiF crystal were $0{\cdot}6 \times 10^{-2}$ per cent of tin and $1{\cdot}2 \times 10^{-2}$ per cent of carbon. Measurements on the refractive indices of the two materials are being made.

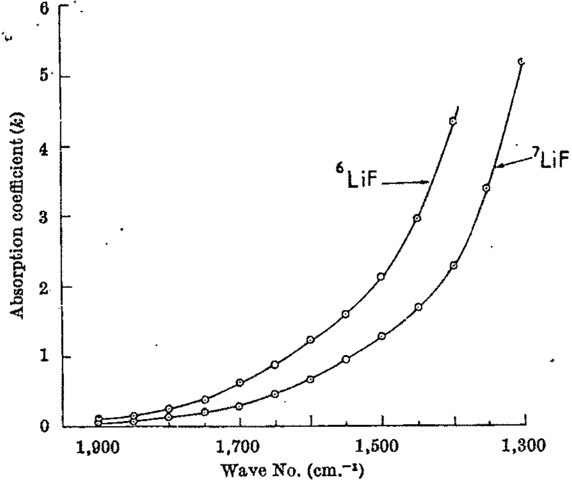

Fig. 2. Variation of absorption coefficient with wave number

We wish to thank the Ministry of Supply for a grant providing the crystal-growing facilities in the Natural Philosophy Department at Aberdeen, and the Chemical Services Department, Capenhurst Works, United Kingdom Atomic Energy Authority, for preparing and analysing the lithium fluoride.

We also thank Dr. D. C. McKean, of the Chemistry Department, Aberdeen, for the loan of a spectrometer equipped for this range, and Mr. W. Mitchell for assistance in the construction and operation of furnaces.

X-Ray Study of Rare Phosphate Minerals

A RARE phosphate mineral assemblage is found in an abandoned mica pegmatite in Sorhee mica mine, north of Laldaiya Pahar (24° 47′ N., 86° 10′ E.; Survey of India, Sheet 72 *L*/1), Monghyr, Bihar. The main pegmatite, worked over a zone of about 200 ft. with a width of nearly 130 ft., intrudes schistose rocks striking N. 25° W. with a dip of about 60° towards W.S.W. The rare phosphate minerals occur as an aggregate, forming bands sometimes more than 2 in. wide and 8 in. long, veined with quartz. The X-ray powder diffraction study shows that the phosphate assemblage consists of graftonite (pale pink) and triphylite (bluish green) with traces of heterosite (purple). A brown mineral, the powder pattern of which is identical with that of rhodonite (manganese silicate), and an unidentified black mineral with rhodochrosite, pyrolusite, hæmatite and amorphous admixtures are also associated in the assemblage.

Penfield[1] first described graftonite, in coarsely laminated intergrowth with triphylite, from a pegmatite near Grafton, New Hampshire. The X-ray single crystal data and powder-spacing data of graftonite, found associated with arrojadite in nickel plate pegmatite, S. Dakota, were reported by Lindberg[2]. Bjorling and Westgren[3] and also Gossner and Strunz[4] gave single-crystal data of triphylite from Varutrask and Hagendorf. Heterosite occurs as a secondary phosphate mineral, formed by the oxidation of triphylite[3,5]. A black lustrous mineral[5,6] occurs as an alteration product of the phosphate minerals, but no detailed examination of this mineral was made.

The unit-cell dimensions (Table 1) were obtained from sets of rotation and zero-layer Weissenberg photographs of a small cleavage fragment of graftonite about the three crystallographic axes. The powder spacing data of this graftonite are identical with those of Rice pegmatite, New Hampshire, and differ considerably from those of Lindberg's nickel plate pegmatite, S. Dakota. The spectrum analysis of this graftonite shows mainly iron, manganese, calcium and phosphorus with small amounts of magnesium, aluminium, nickel, copper, sodium and potassium and traces of lithium, cobalt and tin. Lindberg's chemical analysis of graftonite shows mainly iron, manganese, calcium and phosphorus with small amounts of sodium, aluminium, magnesium and lithium (no potassium) and traces of tin, zinc and copper. The unit-cell dimensions (Table 1) were obtained from sets of rotation and zero-layer Weissenberg photographs about two crystallographic axes of a small cleavage fragment of pale blue triphylite, which is usually unfavourable for single crystal work.

Table 1

* kX.

The powder-spacing data of the purple mineral were found to be identical with those of heterosite from Varutrask pegmatite[3]. The powder-spacing data of the brown mineral correspond almost exactly with those of rhodonite (manganese silicate)[7]. The powder photograph of the dark brown and black mineral grains records faintly the powder lines of rhodochrosite ($MnCO_3$)[8], pyrolusite (MnO_2), hæmatite and a strong broad band or halo, which is characteristic of amorphous admixture associated with cryptomelane; but the powder-spacing data of the main constituent in the black mineral grains do not correspond with those of cryptomelane or of any known manganates or manganese-oxide minerals. The spectrum analysis of the black mineral grains associated with dark brown mineral and traces of quartz shows mainly manganese and iron with considerable amounts of silicon, magnesium, aluminium, calcium and phosphorus, small amounts of potassium, sodium, and copper and traces of vanadium, nickel, silver and platinum (no lithium).

Grateful acknowledgment is made to the Director for kind permission to publish these results, to Dr.

Cultivation of Apple-fruit Tissue *in vitro*

The *in vitro* culture of meristematic tissues derived from roots, tubers, stems, galls and tumours has received much attention, but little is known of the growth requirements of tissues of mature parenchymatous fruit walls (for a definition of the latter term, see ref. 10). The only two tissues of this type which appear to have been cultured are mature avocado pericarp[1] and mature citron mesocarp[2]. In the former tissue active cell division is occurring, but it is unlikely that many cells of the latter tissue are dividing[3]. In the developing apple-fruit, cell-division is completed within 20 days after fertilization, and subsequent growth is due entirely to cell enlargement[4]. In this report the *in vitro* cultivation of tissue derived from apple-fruits both before and after cessation of cell division is described. This appears to be the first successful *in vitro* cultivation of a pome-fruit tissue.

Surface-sterilized fruitlets (diameter *c.* 10 mm.; about 15 days from fertilization) of the varieties Sturmer Pippin, Granny Smith and Cox's Orange Pippin were cut into three pieces by two parallel transverse cuts. The entire centre pieces (thickness 2 mm.) were seated aseptically on agar media (0·5 per cent of Davis agar) with one cut surface contacting the medium. Neither White's medium[5] nor White's medium supplemented with coconut milk induced growth from Sturmer explants. On White's medium[5] supplemented with cysteine 10 p.p.m., calcium pantothenate 0·2 p.p.m., inositol 0·2 p.p.m., biotin 0·2 p.p.m., 2,4-D (2,4-dichlorophenoxyacetic acid) 6 p.p.m., and coconut milk at 10 per cent by volume, explants of all three varieties grew actively. A large number of centres of proliferation developed on the cut surface of cortex and pith. The new tissue has been subcultured and maintained in growth by the liquid-culture technique of Caplin and Steward[6].

Tissue from relatively mature fruits has also been cultured. Disks of tissue (thickness × diameter, 2 mm. × 7 mm.) were excised aseptically from near the equatorial plane of surface-sterilized fruit (variety Sturmer Pippin, 110–130 days from fertilization) so that a sepallary or petallary vascular bundle ran centrally through each explant. The growth-rate of these explants was more than ten times the rate of growth of identically excised explants from the mid-cortex and mid-pith. The medium previously used for the cultivation of fruitlet tissue with the 2,4-D concentration reduced to 1 p.p.m. induced active growth on the surface of nearly all explants. The corresponding medium without coconut milk (medium 1) induced only very slight proliferation on approximately 35 per cent of the explants, the remainder showing no growth. The addition of *l*-asparagine to medium 1 (resulting concentration 150 p.p.m.), yielding medium 2, was slightly stimulative, but no detectable stimulation was produced by the addition of pancreatic digest of casein to medium 1 (resulting concentration 200 p.p.m.), or by doubling the nitrate content of medium 1. A marked stimulation of growth was observed in each case when coconut milk, aqueous extract of immature maize seed or 6-furfurylaminopurine was added individually to medium 2 to give concentrations of 10 per cent by volume, 850 p.p.m. of total solids and 0·2 p.p.m. respectively. Addition of casein hydrolysate to medium 2 did not significantly increase the growth-rate of explants. The further addition of gibberellic acid and 2-benzthiazolyloxyacetic acid (both at three concentrations) did not produce any significant effect.

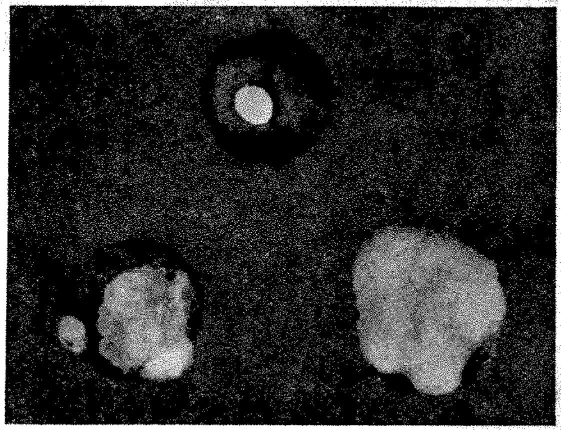

Fig. 1. Sturmer-Pippin explants (excised 110 days from fertilization and cultured on agar media) showing the development of growth from the vascular bundle

The response from coconut milk was probably due to the specific factors present in this fluid which stimulate cell division. If the increased growth-rate was merely due to the presence of additional amino-acid nitrogen, a response to casein hydrolysate might have been expected[7,8]. Removal of 2,4-D from medium 2 supplemented with coconut milk yielded an almost inactive medium. Sturmer apple tissue therefore responds to coconut milk only in the presence of 2,4-D (the effects of other auxins have yet to be investigated). Potato-tuber tissue also has this unusual double requirement for growth *in vitro*[9]. Avocado pericarp and citron mesocarp appear to proliferate *in vitro* without stimulants of the type found in coconut milk[1,2].

The growth of new tissue in culture was mainly from the cut surface of the vascular bundle on the centre of the explant (see Fig. 1). Less active centres of growth sometimes developed on the surface of the explants but their contribution to the total growth was usually small. The new tissue had a white appearance resembling carrot tissue grown on solid media, and was composed of very small cells, about 1/70 of the volume of the explant parenchyma cells. The following varieties, when within 1–3 weeks of maturity, have been cultured on medium 2 supplemented with coconut milk or on this medium with the 2,4-D concentration at 5 p.p.m.; Prince Alfred, Ben Davis, Jonathan, Delicious, Statesman, Dunns and Giant Geniton. Crab-apple tissue (95 days after fertilization) has been cultured on medium 2 supplemented with coconut milk, centres of proliferation being induced on the transversely cut surface of both pith and cortex. Undifferentiated growth has also been obtained from immature seed tissue.

A detailed investigation of the cultivation of apple tissue *in vitro* is in progress. The work reported has been assisted by a grant from the Rockefeller Foundation. Thanks are also expressed to Dr. H. R. Thompson for statistical analyses, to Miss D. A. Bridson for technical assistance, to the American Cyanamid Company for a generous gift of 2-benzthiazolyloxyacetic acid, and to Imperial Chemical Industries, Ltd., for a gift of gibberellic acid.

Temperature Variations in Male Cones of *Encephalartos*

In the hope that this may elicit more information than I have been able to find in the available literature, I give below a summary of observations made on the diurnal rise and fall of temperature in ripe male cones of *Encephalartos altensteinii* Lehm. and *E. lehmannii* Lehm.

Cones cut from plants of *E. altensteinii* growing in the Botanic Gardens, Grahamstown, were used for demonstration purposes during the course of practical work for students of botany, and reference was made to the fact, known to me since childhood, that such male cones, when ripe, become heated. Search of the literature available produced only one reference to this phenomenon[1], in support of my statement, and a rough test was therefore made on a cone to show the truth of the assertion. A thermometer, registering 21° C. in the laboratory, was inserted between the sporophylls of the male cone at a part which was obviously the warmest to the hand: within a matter of seconds, this thermometer registered 35°. During the course of the afternoon, the thermometer registered a rise to 37° (as against an air temperature of 20°) within the cone. This cone was at the stage of shedding pollen and had been removed from the parent plant two days before, being kept on a laboratory bench meanwhile. When discussion with workers whose knowledge of the genus *Encephalartos* is greater than mine, showed that this temperature rise was unknown to them, further rough tests were made on several cones.

These preliminary tests soon showed that besides this remarkable rise in temperature there is a diurnal rhythm, the temperature of the cones rising from about eleven or twelve o'clock in the day, to a maximum about five o'clock in the afternoon, and then falling again until it is the same as, or very close to, the air temperature of the room. The tests were carried out with several cones over a period of several days in the laboratory, and a set of fresh cones was obtained, which gave the same results.

As these were observations made on cones cut from the plant, male cones still *in situ* were also tested. These also showed a great temperature rise and difference between the air temperature and that of the cones, during the afternoon hours.

Tests made on *E. lehmannii* Lehm. do not show the same great rise and fall, but there is apparently some rise of temperature in male cones of this species also. Cones of *E. villosus* were also tested but these were rather far advanced: also, the cones are more open in structure and, perhaps for these two reasons, no results were obtained showing any rise.

A fuller account of these facts will be published later, but if any workers on the Cycadales have information on such a rise of temperature in male cones or know of references in the literature to this fact, apart from the one I have given, their help will be appreciated. It is certainly true, as Gaussen says, that "le cône présente une veritable fièvre", and it would seem that there must be more information either published or known.

Root Nodules of *Coriaria*

The shrubby genus *Coriaria* is one of the eight non-legume Angiospermous genera known to have the capacity of forming root nodules in response to infection from the soil by a symbiotic organism. In some instances, in confirmation of earlier work, the nodules of most of these genera have been shown by my collaborators and me[1,2] to be nitrogen-fixing, but, despite efforts extending over several years, I have not yet raised nodulated plants of *Coriaria* in culture, owing to an apparent difficulty in securing infection of the roots under artificial conditions. However, the results of Kataoka[3] make it probable that *Coriaria* nodules also are nitrogen-fixing.

As pointed out by Good[4] this genus is at present characterized by extreme 'discontinuity' in the sense that it occurs in widely separated regions, chiefly Japan, New Zealand, the Mediterranean region, and Central and South America. So far as I am aware it is only in respect of Japan that records of nodulation in *Coriaria* are to be found in the literature[5]. From correspondence with New Zealand botanists and from material gratefully received from them it is clear that nodulation occurs in that country also. Despite the attention paid by earlier European botanists to the presence of nodules in *Alnus*, *Hippophaë* and *Elaeagnus*, there seems no previous record of the inspection for nodules of the roots of *Coriaria* species native to Europe. Through the good offices of Mr. N. Y. Sandwith, of the Royal Botanic Gardens, Kew, inquiries were made of Dr. P. Montserrat, of Barcelona, with the result indicated in the following communication, which has been translated from the Spanish by Mr. Sandwith.

It has been suggested elsewhere[6] that the geochemical significance of fixation by non-legume nodules must not be overlooked. For example, in New Zealand, which is recognized as deficient in native legumes, the widespread species of *Coriaria* are possibly the main native source of symbiotically fixed nitrogen. The present discontinuous distribution of the genus, noted above, probably indicates that in former times the genus was represented in many regions from which it has now disappeared, and was thus in a position to contribute to the supply of combined nitrogen for plant life in general in many areas.

G. Bond

Botany Dept.,
The University, Glasgow.
June 12.

[6] MacConnell, J. T., and Bond, G., *Ann. Bot.*, N.S., **21**, 185 (1957)

Coriaria myrtifolia, the only species of the genus occurring in the western Mediterranean region, is extraordinarily abundant in the less dense woodlands of the Spanish provinces of Gerona and Barcelona (eastern part) at altitudes of 200–600 m., reaching occasionally to 1,000 m. and also descending in gullies to sea-level. It is more localized in the provinces of Lérida and Tarragona, and rare in more southerly provinces. It occurs, but is not now regarded as native, in Portugal[1]. The species reappears in the western Rif and Algeria, and also in the island of Ibiza[2], while in southern France it extends from the Gironde to the Alpes Maritimes, penetrating into Italy as far as part of the Apennines. Its occurrence in Sicily and Greece is doubtful.

On examining the root systems of young plants of *C. myrtifolia* in two localities, in the provinces of Barcelona and Lérida respectively, clearly evident root nodules were observed, resembling closely those described for Japanese material[3] and others shown in photographs provided by Dr. Bond of New Zealand material. Difficulty was experienced in locating the nodules on old plants.

It may be added that the species attains its optimal development in the humid climates where *Quercus ilex* is dominant. It prefers strong clay soils and is markedly heliophilous, being found especially along the borders of roads, streams and woodland; it is commonly associated with *Prunus spinosa* and species of *Rubus* and *Clematis*, and de Bolós[4] has provided a full ecological study of the *Rubeto–Coriarietum* association.

The fertility of soils where *C. myrtifolia* occurs plentifully is an accepted fact. In some evergreen oak woods the species makes a complete ground cover, and could be of some importance in forest economy if appreciable fixation of nitrogen occurs in the root nodules. It may be noted that thousands of tons of leaves of *C. myrtifolia* were formerly collected each year for use in tanning leather.

Fluorescent Pigment of *Microsporum*

In a previous communication, Wolf[1] reached the conclusion that the fluorescent pigment produced by *Microsporum canis* Bodin and *M. gypseum* Guiart and Grigorakis was a pteridine. The fluorescent substance was extracted from cultures of both fungi grown *in vitro* upon hair and on a synthetic medium. The conclusion as to the pteridine nature of the pigment was based upon ultra-violet absorption spectra, fluorescence spectra, and paper chromatography of a purified material, and is consistent with the results of earlier chemical studies[2,3].

Since then, Chattaway and Barlow[4] have challenged this conclusion, without however adding any new evidence, and have raised questions concerning the nature of fluorescent materials in uninfected hair and in naturally infected hair which neither they nor ourselves can answer at the present time. Recently, Rebell *et al.*[5] have shown that the fluorescent material of rat hair is *l*-kynurenine, but the nature of the fluorescent substance in human hair has not been established. It is the purpose of this communication to present additional evidence as to the pteridine nature of the *Microsporum* pigment derived from infra-red studies and bioassay.

Cultures of *Microsporum canis* and *M. gypseum*, grown upon hair and upon a synthetic medium, were extracted with water by autoclaving for 15 min. The fluorescent material was adsorbed on charcoal, eluted with methanol, and passed through a column of alumina as previously described[1]. The methanol extracts were evaporated to dryness, and potassium bromide pellets containing the fluorescent substance were examined in the infra-red with a Perkin–Elmer model 21 spectrophotometer. The spectra are shown in Fig. 1.

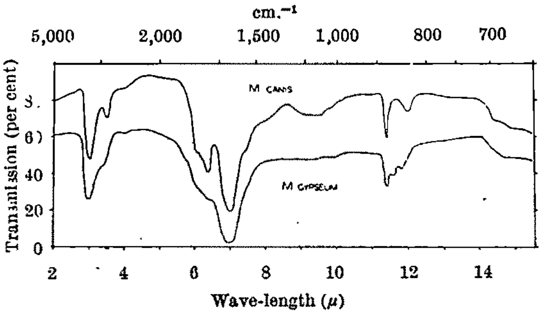

Fig. 1. Infra-red absorption spectra of the fluorescent pigments of *Microsporum canis* and *M. gypseum*

For *M. canis*, the absorption maxima found were as follows: there was a large peak at 3,375 cm.$^{-1}$, indicating an —OH or an =NH group, a small peak at 2,875 (possibly C—H), a shoulder at 1,700 (—CONH$_2$), a medium peak at 1,580 (—NH$_2$), a large peak at 1,440 (possibly C—H), a shoulder at 1,380 (—CONH$_2$), a broad peak at 1,040–1,100 (—NH$_2$), a large peak at 880 and a small one at 840 cm.$^{-1}$ (both of C—H).

The spectrum for *M. gypseum* was quite similar. There was a large peak at 3,375 cm.$^{-1}$, a shoulder at 2,950, a shoulder at 1,580, a large peak at 1,440, a shoulder at 1,350, a large peak at 880 and small peaks at 865 and 855 cm.$^{-1}$. The relatively small number of peaks appears to us to refute the objection of Chattaway and Barlow[4] that our methods of preparation "would almost certainly not effect any great purification of the fluorescent material", and further indicate that our preparations had a purity

Folic acid (1·0 μgm./ml.)	0·10	—	0·85
Pteridine* (1·0 μgm./ml.)	0·10	0·86	—
M. gypseum preparation (0·001 ml./ml.)	—	0·44	0·10
(0·01 ml./ml.)	—	0·84	0·10

* 2-NH_2, 4-OH, 6-trihydroxypropyl pteridine was used here as a source of Crithidia factor.

greater than those examined by Robinson, Figge and Bereston[6] in their infra-red studies of the fluorescent material from *M. audouini*.

Biological verification of the pteridine nature of the compound from *M. gypseum* was obtained by microbiological assay with *Crithidia fasciculata*, a flagellate which requires for growth both a conjugated and an unconjugated pteridine[7]. The finding that preparations from *M. gypseum* possess growth-factor activity for *C. fasciculata* in the presence of low levels (1·0 μgm./ml.) of folic acid, but not in the presence of 'Crithidia factor' (2-NH_2, 4-OH, 6-trihydroxypropyl pteridine) indicates that the compound from *M. gypseum* is an unconjugated trisubstituted pteridine (Table 1). The substituents may be 2-NH_2 or —OH, 4-OH and 6-CH_2OH or a longer aliphatic chain which has two vicinal hydroxy groups. Three of the possible biologically active compounds, 2-NH_2, 4-OH, 6-trihydroxypropyl pteridine[8], compound *A* of Forrest and McNutt[9], and compound *C* of Van Baalen *et al.*[10] are ruled out because of differences in infra-red spectra.

Experimental Ringworm in Guinea Pigs: Oral Treatment with Griseofulvin

In an effort to find a satisfactory agent for the topical treatment of ringworm and other superficial mycoses, many substances, including antibiotics, have been investigated in the past. Although high anti-fungal activity has often been demonstrated by tests *in vitro*, such compounds have given disappointing clinical results when applied topically, and it is now recognized that this is probably due to the inability of such substances to penetrate the keratin of skin, hair and nails to the site of dermatophyte activity. For this reason it has often been suggested that the eventual curative agent will be administered systemically. Wilson[1] states that "the ideal anti-fungal drug even for superficial mycoses would seem to be one which could be safely administered internally in amounts sufficient to endow the cells eventually destined to produce keratin with the power to resist fungi completely, this power persisting as they become keratinized, and the drug thus exerting its effects from within outward".

So far as I am aware there is only one published report of ringworm treatment by systemic means[2] and therefore the following preliminary account of successful treatment of experimentally induced ringworm in animals by oral administration of the antibiotic, griseofulvin, is of interest.

Griseofulvin, a metabolic product of several *Penicillium* species[3], is markedly fungistatic to many fungi *in vitro*[4] and in plants shows systemic antifungal activity[5]. Although little is known about the absorption of griseofulvin when given by mouth, it is reported to have a low mammalian toxicity and it seemed worth while investigating for possible systemic activity in animals.

Guinea pigs were infected experimentally with *Microsporum canis* and treatment with griseofulvin was commenced 10 days later when the lesions were well developed and fluoresced under Wood's light. The antibiotic was administered daily by mouth at a dosage of 60 mgm./kgm.; control animals were given unmedicated tablets. The beneficial effect of treatment was evident clinically within four days of the administration of the first dose of griseofulvin and the highly inflammatory reaction which developed in all the control animals was prevented. Clinical findings were confirmed by killing animals from both the treated and the control group to permit histological examination. In the group treated with griseofulvin about half the hair follicles were infected after four treatments and by the eighth treatment infected follicles were present only very infrequently. Skin sections of the untreated group at these times showed that almost all the hair follicles were heavily invaded by the dermatophyte. It was noted that under Wood's light the infected hairs of treated animals fluoresced only at the tips, and microscopic examination revealed that the dermatophyte was present only in this upper part of the hair shaft. The uninfected basal portion was sharply delimited from the invaded part and malformation of the tips of the dermatophyte hyphæ, characteristic of the effect produced by griseofulvin on susceptible fungi, was seen in a number of hairs cut longitudinally in skin sections. It seems clear that the uninfected part of the hair had been formed during the treatment with griseofulvin and was resistant to invasion by the dermatophyte.

By similar experiments I have found that griseofulvin is equally effective when given orally to guinea pigs experimentally infected with *Trichophyton mentagrophytes*, and it has also been used successfully for the treatment of *T. verrucosum* ringworm induced in cattle[6]. *In vitro*, it is active in low concentrations against all the common dermatophytes.

Further studies are in progress and will be reported elsewhere, together with full details of these preliminary findings. The purpose of this communication is to make available experimental results which may be of some importance for future progress in this hitherto unrewarding field of investigation.

I am indebted to Miss C. O. Dawson, Miss M. Mennie and Miss M. Calder for assistance and to Glaxo Laboratories, Greenford, Middlesex, for supplies of griseofulvin and pharmacological information.

Geographical Colour Polymorphism and Chromosome Constitution in Sympatric Species of Sawflies

The taxonomy of the *arcuata-schaefferi* group of *Tenthredo* sawflies has been a matter of interest both on the Continent[1] and in Britain[2] [3] for some considerable time. The adults are strikingly similar and interspecific differences can be discerned in the females only. Good descriptions of larvæ have not been available for some of the species, and existing accounts in some cases appear vague and confusing, so that doubt exists as to whether reported differences are of inter- or intra-specific rank.

For some time now three members of this group have been the subject of extensive breeding experiments at Queen's College, Dundee, and a full account of the life-histories from egg to adult is now available. Much that is interesting has resulted from this work and some of the facts readily explain previous difficulties in larval identification. Thus it appears that larval colour polymorphism exists in two of the species, namely, *Tenthredo acerrima* Benson and *T. perkinsi* Morice. This polymorphism operates on a simple genetical basis and is related to certain geographical areas of the British Isles. Similarly, in *T. acerrima* intra-specific physiological differences revealed by examination of locomotory activity have resulted in interesting information on the geographical and genetical aspects of such differences.

It has proved impossible to hybridize *T. acerrima* Benson, *T. perkinsi* Morice and *T. arcuata* Forst, and in fact copulation has not been observed although there was ample opportunity for it to occur. Host-plant preference is marked but not absolute, *T. arcuata* and *perkinsi* being associated with white clover (*Trifolium repens* L.) and *T. acerrima* with bird's-foot trefoil (*Lotus corniculatus* L.). The colour and markings of *T. acerrima* larvæ are clearly different from those of either *T. arcuata* or *perkinsi*. In the penultimate instar, however, the larvæ of the last two species resemble each other somewhat, so that it is pleasing to find that there are cytological differences. In *T. arcuata* the male larvæ produced parthenogenetically have a haploid number of 15 chromosomes, whereas female larvæ have a diploid number of 30, but *T. perkinsi*, on the other hand, possesses a haploid number of 18 and a diploid number of 36. Biological, morphological and cytological evidence thus combine to suggest specific rank for these three insects.

In at least one very local and limited area, however, the species *T. acerrima* appears to be variable cytologically as well as morphologically and physiologically. While several *acerrima* larvæ show a haploid chromosome number of 18 and a diploid number of 36, members of one particular brood gave counts of 21 and 42 respectively, possibly the highest number recorded in Tenthredinidae. Inter-breeding of this aberrant brood with 'normal' individuals from the same area gave viable offspring with intermediate chromosome counts. The 'aberrant' and 'normal' parents, taken in the field from the same ecological area, resembled each other in appearance, and the resulting broods of intermediate chromosome count also appeared very similar. It is interesting therefore to find that a survey of the locomotory activity of these same broods showed that they differed in behaviour from what had previously been considered normal for the wild types taken in the area.

Different Frequencies of Supernumerary Chromosomes in Diploid Populations of *Dactylis glomerata* in Israel

Whether supernumerary chromosomes have any selective advantage is still in doubt[1-3]. One possible way of attacking this problem is to find out whether natural populations of a given species show different frequencies of such accessory chromosomes in different ecological habitats.

Dactylis glomerata L. offers favourable material for such an examination. Both diploid ($2n = 14$) and tetraploid ($2n = 28$) forms of this group occur in Israel, where they occupy a rich variety of ecological niches. In diploid plants supernumerary chromosomes of standard size and form are frequently encountered.

Three diploid populations were examined as to the frequency of supernumerary chromosomes in them. In each case, a sample of plants was taken at random in the early winter of 1958, transferred to Jerusalem and examined in the spring. Chromosome counts were made at diakinesis and metaphase I in aceto-carmine squashes of pollen mother cells. The results of this examination are given in Table 1.

The Safad sample was taken from a population growing on the northern outskirts of Safad, Upper

Table 1. Frequency Distribution of Supernumerary Chromosomes in Three Diploid Populations of *Dactylis glomerata* L. in Israel

Locality	Total No. of plants examined	No. of supernumeraries 0	1	2	3	4	Supernumeraries per plant	Supernumerary carriers (per cent)
Safad	75	37	24	11	3	–	0·73	50·70
Mount Kenaan	31	23	5	1	2	–	0·42	25·80
Jerusalem	80	57	20	2	1	–	0·34	28·75

Galilee. The plants were growing on a steep north facing slope, altitude 750 m., and on light Rendzina soil derived from chalky Senonian bedrock.

The Mount Kenaan sample was collected approximately 2 km. north of Safad. This place is characterized by terra-rossa soil on hard Eocene limestone. Plants were taken from the top of a hill, altitude 950 m.

The Jerusalem sample was collected in the Valley of the Cross (Matzleva) on the western outskirts of the city. Plants were growing on a gentle slope facing west, altitude 700 m., on terra-rossa soil derived from Upper Cenomanian dolomites and limestones.

The results indicate striking differences between Jerusalem and Safad populations. Most suggestive, however, is the comparison between Safad and Kenaan. Populations here are only 2 km. apart but found on completely different soils. At the 5 per cent level, the data indicate significant differences even between these two geographically close populations. (χ^2 test for homogeneity, plants with 2 and 3 supernumeraries grouped together: $\chi^2 = 6{\cdot}31$; $P \sim 0{\cdot}03$.) On the other hand, the Jerusalem and Kenaan populations seem very similar.

The examination suggests that *Dactylis* populations occupying different ecological habitats do differ from one another in regard to the frequency of supernumerary chromosomes. Such a difference could be attributed to different selective advantage of supernumeraries in different habitats.

Spray-collecting Area of Locusts and their Susceptibility to Insecticides

LOCUST swarms may be sprayed with insecticides when the insects are settled or in flight. Techniques have been developed for the estimation of the amount of spray collected by individual locusts[1-4], and fundamental to their interpretation is the spray-collecting area of a locust. Two areas have been used for calculations: the plan area for settled locusts[1,2], reduced to allow for the less vulnerable parts, and the 'horizontal equivalent area' for flying locusts[3,4], defined as the horizontal plane area which, when passed through a given spray of droplets with the same velocity as a locust, collects the same number of droplets as the locust. The plan area of the desert locust, *Schistocerca gregaria* (Forsk.), is about 6½ cm.², and the horizontal equivalent area has been found experimentally to vary greatly with drop size, increasing from 30 cm.² for droplets 300μ in diameter to 450 cm.² for 50μ drops[5]. The collecting surface of a settled locust approximates to the plan area when the drops are falling nearly vertically, but at shallow angles of approach the quantity of spray deposited on the locust is many times that estimated from area dosage and plan area.

A development relating these parameters is the consideration of an area normal to the path of approach of the drops to the locust, the path of approach depending on the terminal velocity of the drops and the air-speed of, or wind-speed over, the locust. This 'normal equivalent area', a term suggested by Mr. K. F. Sawyer, may be defined as the area of a plane surface, at right angles to the path of approach of the drops, through which pass as many drops as are collected by the locust under similar conditions. Laboratory measurements of this area (see Table 1) can most easily be made by comparing the quantity of spray picked up by a locust with the quantity deposited on a sphere under the same conditions, due allowance being made for the droplet-collecting efficiency of the sphere.

Table 1. THE SPRAY-COLLECTING AREAS OF THE LOCUST (CM.²)

Settled locusts

Plan area for 10 males, 5·5; 10 females, 7·3. Normal equivalent area for randomly orientated locusts (spray droplets of 50–230μ and wind speed of 2 m./sec.) 5–6

Flying locusts

	Drop diameter (μ)			
	50	100	200–230	300
Horizontal equivalent area (ref. 5) (♂ and ♀)	445	110	46	31
Normal equivalent area (ref. 5) ♂	8·6	8·7	9·4	—
♀	9·9	11·0	11·2	—

In experiments with settled locusts, of unconstrained and variable orientation, the mean horizontal equivalent area was found to be 5–6 cm.² for uniform sprays from drops of 50, 100 or 230μ in diameter drifting over the locusts at 2 m./sec. At lower wind-speeds the values of the normal equivalent areas were reduced owing to a decreased collection efficiency of the locusts. For locusts flying through a falling spray, the normal equivalent area was found to be about 9 cm.² for males and 10½ cm.² for females, being virtually independent of the droplet diameter over the range 50–230μ.

The deposit on a locust from a uniform spray will be given by the product of the normal equivalent area, concentration, and path-length through the spray. The relative quantity of spray picked up by flying and settled locusts subjected to the same concentration of spray at the same relative wind speeds will be proportional to their normal equivalent areas. The flying locusts therefore collect nearly twice as much spray as the settled ones. Furthermore, the deposit on a settled locust can be expected to exceed the corresponding area dosage on a horizontal surface by a factor approximating to the cosecant of the angle of approach of the spray, measured from the horizontal.

When a 20 per cent solution of the insecticide 4 : 6-dinitro-*o*-cresol (DNC) in oil is sprayed over locusts, a decrease in size of the sprayed droplets from 300 to 100μ in diameter appears to cause an increase in the toxicity of the spray to both the flying and settled insects, as is shown in Table 2. The insecticide diazinon exhibits little change in toxicity with drop diameter when sprayed over flying locusts.

Table 2. *LD*50's OF INSECTICIDES SPRAYED ON TO *S. gregaria* (μgm./gm.)

Approximate drop diameter (μ)		50	100	215	300
Locusts settled	DNC	23*	25*	26*	35
	Diazinon	—	—	6·6*	—
Locusts flying	DNC	—	16	21	30†
	Diazinon	5·4	6·0	5·6	—

* Insects constrained to lie with long axis perpendicular to path of approach of the drops.

† Ref. 5.

Combining the differences in collecting area and susceptibility, the flying locusts are thus about 2·4 times as vulnerable to sprays of 4 : 6-dinitro-*o*-cresol solution as are settled ones and about twice as vulnerable to diazinon. The difference is further enhanced when the application of these results to a particular spraying operation is considered, owing to the wind gradient near the ground which effectively reduces the path-length of the settled locusts through the spray and may also reduce their normal equivalent areas. In actual field operations with aircraft, this increased vulnerability is, at times, more than counterbalanced by the low densities of flying swarms with consequent very low kills per gallon of insecticide.

I should like to thank Dr. R. C. Rainey and Dr. T. H. C. Taylor for their advice and encouragement during the preparation of this communication.

Microscopic Structure of the Lungs of the Bottlenose Whale

One of the most remarkable structures in the lungs of Cetacea are the sphincters in the respiratory bronchioles. In a number of toothed whales (Odontoceti) the mucosa of these terminal bronchioles shows 8 to 40 consecutive ring-like folds with a circular layer of smooth muscle fibres acting as a sphincter. They may close the passage in the bronchiole completely. They divide the lumen in a number of small consecutive chambers. When the musculature relaxes the passage is re-opened by a system of radially directed elastic fibres, running from the muscular layer to the peripheral layer of cartilage. The sphincters have been described in the common porpoise (*Phocaena phocaena* (L.)), the bottlenose dolphin (*Tursiops truncatus* (Mont.)), the common dolphin (*Delphinus delphis* L.), *Prodelphinus caeruleo-albus* Meyen, the white whale (*Delphinapterus leucas* (Pallas)) and in *Berardius bairdii* Stejneger[1,4-9]. Several authors showed that these sphincters are not present in baleen whales (Mystacoceti)[2,6,7,9]. These animals show a very well-developed mass of muscular fibres in the tips of the alveolar septa. Probably these fibres are able to close the alveoles completely.

Murata[6] found a constriction in a respiratory bronchiole of the sperm whale (*Physeter macrocephalus* L.). This constriction was not found by other authors[2,9], and all agree that the typical system of consecutive sphincters is not present in the sperm whale. This fact suggests that the occurrence of the sphincters is not connected with the systematic position of the animals, but with functional aspects. The dives of whalebone whales and the sperm whale are deep and prolonged, and the animals have a lung capacity of about 50 per cent of that of the terrestrial mammals[3,7]. The other toothed whales do not dive very deep and very long. Their lung capacity is about 150 per cent of that of the land mammals.

To prove the above suggestion we studied the microscopic anatomy of the lungs of the bottlenose whale (*Hyperoodon ampullatus* (Forster)), a toothed whale characterized by deep and prolonged diving which has a very small lung capacity, like the sperm whale. Prof. J. T. Ruud kindly provided us with the lungs of an animal captured at the land station Steinshamn (Norway). The material was not very well preserved, but all essential characteristics could be determined.

As in all other Cetacea the connective tissue of the lungs was highly elastic. There was practically no lymphoid tissue. The bronchial epithelium and the glands contained almost no mucoid cells. These characteristics may be a result of the absence of dust in the aspired air[7]. The septa of the alveoles showed two layers of capillaries and many elastic fibres. As in Mystacoceti the tips of the septa contained a large amount of smooth musculature.

All bronchiæ showed a ciliary epithelium. At their outer side they were surrounded by a layer of irregularly shaped pieces of cartilage. This cartilage was also found in the terminal bronchioles as in all other Cetacea with the exception of *Berardius*[6]. On the inner side of the cartilage there is a layer of elastic connective tissue with a very distinctive plexus of anastomosing arteries. This arterial plexus is found even in the smallest bronchioles. The walls of the vessels are very elastic. *Delphinus* and *Phocaena* possess a venous or a capillary plexus[4,5]. The plexuses may act as shock-absorbers and they may also serve for heating the air.

At the inner side of the plexus is a very well-developed longitudinal layer of smooth musculature, as is the case in the terminal bronchioles. There are, however, no circular folds of the mucosa. Consequently the typical consecutive sphincters are absent in the bottlenose whale.

This phenomenon shows that the sphincters do not occur in animals characterized by deep and prolonged diving and of small lung capacity. They are found only in frequently breathing toothed whales with a large lung capacity. A system of consecutive cocks is used in technical constructions with great differences in pressure at either side of the cock. If the pressure must be regulated by opening the cock now and then, a series of consecutive cocks is preferable to a single one. It is highly probable that the system of sphincters must be considered as an adaptation to fluctuations of the air-pressure in the lungs during quick and frequent diving and emerging, and especially during the violent inspiration and expiration of Cetacea with a very large lung capacity.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Experimental Officer (male, under 28 on December 31, 1958, with a degree in forestry or botany with subsidiary chemistry, and an interest in ecology and Scottish woodlands), for work on forest ecology and management of woodland reserves in Scotland—The Nature Conservancy (E), 19 Belgrave Square, London, S.W.1 (August 22).

Lecturer (with a degree in botany or in agricultural botany, teaching and/or research experience, and preferably experience in genetics and plant breeding) in Agricultural Botany in the Department of Agriculture, Kumasi College of Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (August 22).

Research Fellow or Senior Research Fellow in the Department of Pure Mathematics—The Registrar, The University, Birmingham 15 (August 22).

Senior Lecturer or Lecturer (with a degree in veterinary medicine, teaching and/or research experience, and preferably experience in a tropical country) in Veterinary Science in the Department of Agriculture, Kumasi College of Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (August 22).

Senior Lecturer (with a good honours degree and teaching experience) in Applied Mathematics at the Nigerian College of Arts, Science and Technology—The Secretary, Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (August 22).

Head (well qualified in either chemistry or metallurgy and with appropriate teaching and industrial experience) of the Department of Pure and Applied Science—The Principal, The Chance Technical College, Crocketts Lane, Smethwick (August 23).

Senior Lecturer in Radiochemistry at the New South Wales University of Technology, Kensington, New South Wales, Australia—The Agent General for New South Wales, 56 Strand, London, W.C.2 (Australia, August 25).

Lecturer in the Department of Mathematical Physics—The Secretary, The University, Edinburgh (August 29).

Assistants (2) in Chemistry (one Inorganic and one Physical)—The Secretary, The University, Aberdeen (August 30).

Assistant Lecturer (with special qualifications in organic chemistry) in Chemistry—The Registrar, The University, Manchester 13 (August 31).

Biometrician with the Government of the Federation of Rhodesia and Nyasaland, for duties which will include design of experiments in all phases of agriculture and animal husbandry research and analysis of data and related statistical practice—The Secretary (*R*), Rhodesia House, 429 Strand, London, W.C.2 (September 7).

Assistant in Statistics—The Secretary, The University, Aberdeen September 12).

Lecturer (preferably with experience and interests in cytogenetics) in Botany at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 12).

Assistant Lecturer (with special qualifications in applied mathematics) in Mathematics—The Registrar, The University, Manchester 13 (September 15).

Lecturer or Assistant Lecturer in Geology at the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 15).

Lecturer or Assistant Lecturer in Pharmacology at the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 15).

Chair of Chemistry—The Secretary to the Curators of Patronage, The University, 4 Albyn Place, Edinburgh 2 (September 30).

Chair of Laryngology and Otology at the Institute of Laryngology and Otology—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 31).

Assistant Experimental Officer (with a degree in chemistry or agricultural chemistry or equivalent qualifications), to carry out chemical analyses of soils and plants; and an Assistant Experimental Officer or Experimental Officer, for biological work in connexion with the study of strains of insects resistant to insecticides—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Assistant, Grade B, in the Electrical Engineering and Physics Department, Coventry Technical College, to teach physics in National Certificate, Sandwich and Degree Courses to full-time, part-time day and evening students—Director of Education, Council Offices, Coventry.

Assistant Lecturer and Demonstrator in Physiology—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

Assistant Warden (male, with a degree in zoology, and an interest in ornithology and marine or freshwater biology, and preferably some research experience) at Flatford Mill Field Centre; and a Field Assistant (female, with a university degree in geography or natural sciences)—The Secretary and Treasurer, Field Studies Council, Balfour House, 119–125 Finsbury Pavement, London, E.C.2.

Biologist (with postgraduate experience of experimental animal work), for cancer research—Prof. K. R. Hill, Pathology Department, Royal Free Hospital, London, W.C.1.

Head of the Bacteriology Department—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 58/23.

Organic and Physical Chemists, for research in the following fields: colloid chemistry of latex and related emulsions, polymerizations in emulsions and solid systems, mechanism of the ozonolysis of organic compounds and its control—The Director of Research, British Rubber Producers' Research Association, 48–56 Tewin Road, Welwyn Garden City, Herts.

Organic Chemist (honours graduate with Ph.D. or equivalent research experience, preferably in synthetic work), to join in research on biological action and molecular structure of organic compounds—Dr. C. J. W. Brooks, Clinical Chemotherapeutic Research Unit, Medical Research Council, Western Infirmary, Glasgow, W.1.

Reader in Mechanical Engineering, and a Reader in Electrical Engineering—The Principal, The Institute of Technology, Bradford 7.

Research Assistants (with a good honours degree), to carry out fundamental research in (*a*) problems in organic chemistry and (*b*) electronics, high vacuum problems or interferometry—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham.

Technical Research Assistant in the Physiology Department—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

Technician (with experience in histological and photographic techniques, and preferably also in the general work of an anatomy department) in the Anatomy Department—The Secretary, Guy's Hospital Medical School, London Bridge, London, S.E.1.

ION EXCHANGE RESINS FOR CHROMATOGRAPHY

A complete range of "Zeo-Karb 225" and "De-Acidite FF" ion exchange resins for chromatographic separations and other analytical purposes is now being produced by The Permutit Company Ltd. A new production unit has been established especially for this purpose. Details of the resins are shown in the table on the right.

The crosslinking of "Zeo-Karb 225" cation exchange resins is given in terms of nominal weight percentage of divinylbenzene in the hydrocarbon polymer. The corresponding weight swelling or water regain is also given.

Only the weight swelling, or water regain is specified for the "De-Acidite FF" because extra crosslinks, in addition to those originally placed in the hydrocarbon structure, are introduced during manufacture. It is thus not possible to produce "De-Acidite FF" in as wide a range as "Zeo-Karb 225" because materials with very high water regain are difficult to manufacture reproducibly.

"ZEO-KARB 225"

An Important
PRICE REDUCTION
The Nivoc Automatic Aperiodic Balance is now priced at **£135**

The **Nivoc Automatic Aperiodic Balance,** capacity 200 g, sensitivity 0·1 mg, not only incorporates an entirely new principle of weight pre-selection but, in addition, has a wide range scale 0–300 mg which indicates directly to 0·1 mg by means of an auxiliary scale. This, combined with an average 'period' of 10 seconds, will surely commend the Balance to discerning users requiring an extremely rapid and accurate instrument.

- **Eliminates weights below 300 mg**
- **Weight errors negligible**

We will willingly demonstrate its capabilities on request

LECTURES AND COURSES

THE POLYTECHNIC

309 REGENT STREET, W.1

DEPARTMENT OF MATHEMATICS AND PHYSICS

A course of Lectures on ELECTRONICS will be held on Wednesday evenings from 6.30 to 8 p.m., commencing September 25, 1958. The course is suitable for those who wish to take this subject in the Graduateship examination of the Institute of Physics. Fee for the course: £2.

A Practical course on ELECTRONICS will be held on Thursday evenings from 6 to 9 p.m., commencing September 26, 1958. Fee for the course: £2.

A detailed syllabus of the lectures is available. Application to attend the course should be made as soon as possible to the Director of Education.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

SANDWICH COURSE IN CHEMISTRY

The Sandwich Course in preparation for the examination leading to Graduateship of the Royal Institute of Chemistry commences on September 22, 1958. The course (works based) is of four years' duration and involves six-months' study at College each year. The normal requirements for admission to the course will be successes at " A " Level (G.C.E.) or comparable examinations, in chemistry, physics and mathematics and three suitable ordinary level subjects.

Inquiries from industrial firms, research organizations, and government departments will be welcomed. Particulars from the Secretary, Chelsea College of Science and Technology, Manresa Road, S.W.3.

UNIVERSITY OF LONDON

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE

MIDDLESEX HOSPITAL MEDICAL SCHOOL

COURSE FOR M.SC. DEGREE IN RADIATION PHYSICS

An intercollegiate course for this degree will commence in October, 1958, in the above schools of the University.

The course, which extends over one or two academic years, will comprise lectures and practical work in nuclear physics and the properties, interactions and applications of ionizing radiations. It is designed as a part-time course involving attendance up to six hours per week for graduates working with radiations in medicine and industry, and a B.Sc. degree in physics is required for registration. Appropriate research facilities will be available for certain selected students.

The fee will be 10 guineas per academic term. Applications for registration should be made either to Professor J. Rotblat at St. Bartholomew's Hospital Medical College, Charterhouse Square, E.C.1, or Professor J. E. Roberts at Middlesex Hospital Medical School, Mortimer Street, W.1, from whom further particulars may be obtained.

UNIVERSITY OF BRISTOL

DIPLOMA IN HORTICULTURAL SCIENCE

DIPLOMA IN PLANT PATHOLOGY (including ENTOMOLOGY AND PROTECTION)

The above postgraduate Diploma courses will be available during the session 1958-9. Conducted in part at the Long Ashton Research Station, they are intended primarily for those with good honours degrees in science who seek careers in horticultural research, at home or overseas. The course in Plant Pathology and Protection permits specialization in any approved branch of the subject, including applied entomology. The Horticultural Science course commences on September 15, the Plant Pathology course on September 29. Both courses extend over a full session of three terms ending in June or July, and include some additional practical work during the vacations. Time is allowed during the summer term for some original investigation.

Early application for the remaining vacancies should be made to the Registrar, the University, Bristol 8, from whom full particulars and entry forms may be obtained.

UNIVERSITY OF MANCHESTER

The next session commences on Thursday, October 2, 1958.

OFFICIAL APPOINTMENTS

UNIVERSITY OF ALBERTA HOSPITAL

EDMONTON, ALBERTA, CANADA

Applications are invited for the position of Assistant Director of the Clinical Laboratory Services. The duties will be concerned with the future development of the biochemistry laboratory service in the hospital, consulting and advising on clinical problems and research projects involving biochemistry and teaching. A teaching appointment in the University of Alberta Medical School, while not automatic with this appointment, is customary. There will be ample opportunity to carry on individual research. The qualifications required are a degree in medicine and special training and experience in biochemistry. Preference will be given to those holding the M.R.C.P. or F.R.C.P. or a doctorate degree in biochemistry. Male, age 30 to 40 preferred but not essential. Salary $10,000 to $12,000 per annum.

Further details may be obtained from Professor E. J. King, Postgraduate Medical School, Ducane Road, W.12, London, England. Interested parties should apply to the Medical Superintendent, University of Alberta Hospital, giving full details and the names of two references.

ARCS, PLASMA, SOLID STATE PHYSICS

Posts in the above fields are available for young graduates in physics, or in electrical engineering with strong interest in physics, preferably with Ph.D. or equivalent experience.

(1) For research into the physics and applications of high power arcs and discharges. (Laboratory at Greenford, Middlesex.)

(2) For research into the mechanism of conduction through insulating material. (Laboratory at Leatherhead, Surrey.)

Salary up to £900 per annum at Ph.D. or equivalent level. Superannuation under F.S.S.U.

Apply, stating post in question, to the Secretary, Electrical Research Association, Cleeve Road, Leatherhead, Surrey.

COUNTY BOROUGH OF BRIGHTON EDUCATION COMMITTEE

BRIGHTON TECHNICAL COLLEGE

Principal: G. E. Watts, M.A., Ph.D.(Cantab), B.Sc.(London), F.R.I.C.

CHEMISTRY DEPARTMENT

Head of Department: E. G. Cowley, M.Sc., Ph.D.(London), F.R.I.C.

RESEARCH ASSISTANTSHIP IN CHEMISTRY

Applications invited for Research Assistantship in Chemistry value £300 per annum, with additional remuneration for demonstration work not exceeding six hours weekly. Applicants should possess the B.Sc. (Special Chemistry) Degree of the University of London. Appointment for one year, renewable for further period subject to satisfactory progress. Selected candidate required to work for higher degree on approved physicochemical project.

Forms of application, obtainable from the Registrar, Brighton Technical College, should be returned to him as soon as possible.

W. G. STONE,
Director of Education.

UNIVERSITY OF ABERDEEN

Applications are invited for two Assistants in Chemistry (one Inorganic and one Physical). Salary on scale £700 to £850. F.S.S.U. and child allowance.

Particulars from the Secretary, the University. Aberdeen, with whom applications (two copies) should be lodged by August 30, 1958.

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS

Assistant Experimental Officer to carry out chemical analyses of soils and plants. Degree in chemistry or agricultural chemistry, or equivalent qualifications. Starting salary between £550 (age 23) and £645 (age 26 or over) on scale rising to £800. Superannuation scheme.

Apply to Secretary, giving names of two referees.

COMMONWEALTH of AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF INDUSTRIAL CHEMISTRY

APPOINTMENT OF CHEMICAL ENGINEER

Applications are invited for appointment to a position of Chemical Engineer with the Organization's Division of Industrial Chemistry located at Fishermen's Bend, Melbourne. The appointee will be responsible, under direction from the research staff, fpr the work of a small team engaged in process and equipment development within the Division's Chemical Engineering Section. This Section is undertaking research and development work covering a wide range of chemical engineering activities. Applicants should possess a university degree or a technical college diploma in science or technology, together with wide experience in chemical engineering techniques. Dependent upon qualifications and experience, commencing salary will be determined within the salary range of Experimental Officer, Grade III, £A.1,786 to £A.2,006 per annum. Salary for a female appointee would be £A.170 per annum less than the corresponding male rates. For an outstanding applicant, a higher classification and salary will be considered. The appointment will be conditional upon a satisfactory medical examination and the appointment carries with it Commonwealth Superannuation Fund or Commonwealth Provident Account privileges. Fares to Australia, including those of wife and dependent family, will be provided by the Organization. Details may be discussed with the undersigned.

Applications, quoting Appointment No. 590/680, and stating full name, place, date and year of birth, nationality, marital state, present employment, details of qualifications and experience, and of war service, if any, together with the names of not more than four persons acquainted with th applicant's academic and professional status sho reach the undersigned, from whom further r ticulars may be obtained, by September 19, 19

E. J. DRAKE,
Chief Scientific Liaison Offic
Australian Scientific Liaison Office,
Africa House, Kingsway, London, W.C.2.

UNIVERSITY OF MELBOURNE

READERSHIP IN STATISTICS

The University of Melbourne proposes to make an appointment to a Readership in the Department of Statistics and invites inquiries from statisticians with suitable qualifications and experience who might desire to be considered for the post. The salary range is £A.2,560 to £A.2,800 with annual increments of £A.50, the commencing salary to depend on the experience of the appointee. Some Departmental consulting work, if undertaken by the appointee, may be remunerated from the appropriate fee payable to the University.

The position will be filled by invitation and it is desired to make the appointment as soon as possible. Details regarding the conditions of appointment may be obtained from the Professor of Statistics, University of Melbourne, Carlton, N.3, Victoria, Australia. It would expedite matters if, when writing, full particulars of career and of teaching and consulting experience were to be given, together with the names of two or three people who might subsequently be appealed to as referees.

F. H. JOHNSTON,
Registrar.

ROYAL NAVAL SCIENTIFIC SERVICE Requires Senior Scientific Officers and Scientific Officers for Establishments in London area, Baldock, Portsmouth, Portland, Poole, Greenock and Rosyth. Main requirements are about 25 vacancies for Physicists, Electronic Engineers and Mathematicians in areas specified. The following particular vacancies also exist: Mechanical Engineer for work on gas turbine problems in the London area. Mechanical Engineers for work on design and development of U/W devices in Portland area. Metallurgists for Rosyth and Poole. Chemists (Physical and Inorganic) for Poole area, Baldock and London. Candidates must normally be natural born British subjects of natural born British parents, with at least first- or second-class honours degrees or equivalent high professional attainments. Senior Scientific Officers must have had at least three years' postgraduate experience and be not less than 26 years of age. Salaries (men): Senior Scientific Officer, £1,190 to £1,410; Scientific Officer, £635 to £1,110 (London)—somewhat lower in provinces. Appointments unestablished (with F.S.S.U. benefits), but opportunities may occur for those between the ages of 21 and 32 to compete for established posts.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A98/8A.

TECHNICAL EDUCATION AND SOCIAL CHANGE

IN his Hinchley Memorial Lecture last autumn on "An Education for Our Times", Dr. R. P. Linstead argued that any good system of education would give a good product out of good material, against a good social background; and by a good system of education he meant one starting in breadth and proceeding in depth in the honest study of genuine academic subjects. Dr. Linstead pointed out that in any system of higher education there would be gaps and shortcomings in regions outside the specialist subjects, and these gaps would be most noticeable where the talent is thin or the cultural and social background insecure. This is, he observed, one aspect of the general problem of the incapacity of man to keep up with the growth of knowledge and to adapt himself to the complexity of the world.

The universities in Britain have been increasingly aware of the close relation between their work and the social and cultural background of their students. The widening strata of society from which their students are drawn involve changes in the assumptions in their teaching and in the demand made on some of their institutions, for example, the university library, just as social change may involve changes in the content and the extent of their faculties. Not the least merit of Dr. Linstead's lecture was the way in which he showed how easy it is, without foresight, for such changes or new demands to place impossible burdens upon the universities, and to involve expenditure out of all proportion to the return to the community.

If, however, the provision of a broad general education has forced increasing attention to the bearing of social change on education—at least so far as the universities are concerned—the relation between technical education and social change has received comparatively little attention. Dr. S. F. Cotgrove's recent study of that subject* is therefore to be warmly welcomed, in that it directs attention to factors of supreme importance in considering the provision of trained man-power. Moreover, this fresh approach is in itself suggestive of new ideas; and although in the main Dr. Cotgrove is essentially factual, here and there he hints quite plainly if less forcefully than Sir Hugh Beaver did recently, that in education, for all our protestations, there is in Great Britain neither a national policy nor the national organization to secure one.

To read the recent report of the Minister of Education on "Education in 1957"†, bearing in mind that Scotland is excluded and that the chapter on university awards is now limited to arts subjects, since the Department of Scientific and Industrial Research took over the responsibility for science awards, is to realize how fully justified are Sir Hugh's strictures and the quieter comments of Dr. Cotgrove. What stands out from all three documents is the importance of dealing with education as a whole, and the danger and waste of sectionalism, whether geographical, administrative or disciplinary. There is at present no official means of securing a comprehensive view of the whole field or, short of Cabinet level, for securing concerted action if needed.

Sir Hugh Beaver devoted almost half his lecture on "Science and the State", given before the Institution of Chemical Engineers, to the question of education, showing how the production of an adequate supply of scientists and technologists depends on an effective national policy for education. In the absence of such a policy and the means to concert and to execute one, our hope of increasing the supply of scientists and technologists depends upon the agreement of a large number of departments, authorities, schools, colleges and other bodies that such an increase is necessary (and Sir Hugh might have added that many such bodies are dominated by people with no first-hand appreciation of science or technology); the immediate provision of the finance; and an adequacy of teachers. Sir Hugh Beaver emphasized the critical importance of the supply of teachers, but also referred to the inadequate equipment for science teaching of many schools, and finally stressed that the Minister of Education has neither the responsibility for concerting a policy to produce the technologists and scientists required, nor the necessary scientific advice.

That may be true, but the value of the Ministry of Education's report should not be under-estimated. It shows, very clearly, trends of which due account has to be taken even when we seek elsewhere the means for concerted policy and action. More boys and girls are now staying at school beyond the age of fifteen, and they are staying longer. Moreover, a graph given in the report indicates that, in consequence of the rise in the birth-rate during the past few years, the Ministry of Education is now expecting in ten years time a peak in the school population almost as high as that expected for 1961. A situation originally expected to be temporary may thus prove much more nearly permanent and require more permanent measures of treatment.

On top of this, in spite of record progress in school building, including a number of projects specifically to provide additional science accommodation, and a slight improvement in the staffing position in the primary schools, the staffing position in the secondary schools continued to deteriorate. With increasing recruitment and a record number of teachers in the maintained schools, the effect was only marginal, and the situation remains particularly critical as regards teachers of mathematics and science. The number of such teachers increased, nearly 400 more students concentrated on these subjects in their final year in college, and more than twice as many trained teachers attended the special supplementary courses; but the result was merely to prevent any further deterioration in the relevant staffing standards. A recent debate in the House of Commons on the possible deferment from National Service of third-class honours graduates in mathematics in order to enable them to take up teaching posts merely stressed the shortage of such graduates and the keen competition between teaching and Service training rather than held out hope of any relief from this direction.

---

* Technical Education and Social Change. By Dr. Stephen F. Cotgrove. (Studies in Society.) Pp. 220. (London: George Allen and Unwin, Ltd., 1958.) 25s. net.

† Education in 1957: Being the Report of the Ministry of Education and the Statistics of Public Education for England and Wales. Pp. v+198. (Cmnd. 454.) (London: H.M. Stationery Office, 1958.) 9s. net.

Dr. Cotgrove is concerned with technical education rather than with education as a whole; but his survey brings out the dependence of technical education upon what is done in the schools. He provides ample evidence in support of Mr. J. J. B. Dempster's contention, in writing on the secondary modern school in a symposium of articles on the "Educational Framework of an Industrial Society" in *Research*, that if industry is to have the skilled personnel it needs and the secondary schools are to come into their own, a great deal depends upon the skill with which appropriate stimuli are sought and applied, and upon the pattern within which teachers in the secondary modern schools are called upon to work. This point seems to elude Mr. John Wellens in commenting on the series of articles, although he recognizes that secondary modern schools should, and were intended to, provide for the special needs of their pupils and that the secondary technical schools cannot make their full contribution to the supply of technologists unless they receive their proper quota of good students. Moreover, emphasizing that the correct preparation for a study of advanced technology is a good grounding in science and mathematics, Mr. Wellens points out that it is the grammar and public schools that have offered the best preparation for the study of technology, and accordingly the more adequate the secondary technical school becomes in training potential technologists, the nearer it will approach the grammar school.

That of itself should suffice to give pause to some of the attacks on the grammar school which are being made in the name of political dogma, and there is more to that end in Dr. Cotgrove's study. Two of his most valuable chapters are those in which he examines the recruitment of students and in particular the influence of secondary education on the recruitment of students to the technical colleges. Earlier chapters trace the stagnation in technical education in Britain before the 1930's—and even down to 1945—to the indifference and even apathy of industry. During the war years and from 1945 onwards, the changing attitude of industry to research and the increasing application of science to production have resulted in an increased demand for scientific man-power, which has been accompanied by a substantial increase in the attendance of students, both full-time and part-time, at courses in science and technology at the technical colleges and universities. Then Dr. Cotgrove seeks to examine the mechanisms by which the needs of industry for scientists and technologists are translated into the decisions of students to attend the appropriate courses, and to analyse the factors determining the recruitment of students to the technical colleges.

Dr. Cotgrove's survey indicates that, although the main motive in attending technical colleges is the expectation of occupational reward, occupation is the main factor determining attendance. The failure to attract manual workers is attributed to the small rewards in manual occupations for qualifications achieved, and to the fact that most students attend classes to get on in their jobs rather than to change their occupations. Nevertheless, social factors such as social origins can reduce considerably the potential supply of students in science and technology, though among part-time students this appears indirectly in the influence of social origins on entry to occupations and the association between occupation and part-time attendance. The social factors appear most marked in Dr. Cotgrove's survey of the polytechnics; but they also appear in the recruitment to various courses within the technical colleges.

This influence of social class was emphasized three years ago in the report on early school-leaving, as was the wastage through the failure to complete courses for which students have entered. Dr. Cotgrove suggests that attendance might be increased and wastage reduced by greater encouragement and assistance from employers, especially in the form of giving time off for the older students. In this connexion it may be noted that the report of the Ministry of Education records increases of 9 per cent in the number of young employees who attended part-time day release courses in working hours and of 13 per cent in the number of students attending full-time (including sandwich) courses. Sandwich courses now number 203 compared with about 100 when the White Paper on technical education was issued.

Dr. Cotgrove also brings out a close association between secondary education and further education. The grammar school 'leaver' is orientated both towards the universities and towards university courses in the technical colleges, and recruitment to the technical colleges and to courses in science and technology appears to have been hindered by the persistence of the educational and social values of the nineteenth century mediated by the grammar schools. Like the Advisory Council for Scientific Policy in its report for 1951–52, Dr. Cotgrove comments that the study of arts has enjoyed a higher prestige than science, while the superior prestige of science compared with technology has decreased still further the attraction of technical college courses to the grammar school leaver. This is due in part to the pressure by parents for courses leading to 'black-coated occupations' in commerce, finance and the professions; and the recent decline in the proportion of students which the technical colleges draw from the grammar schools and the secondary modern schools has been accompanied by a decline in the proportion of university and other advanced work in the colleges.

Pursuing this inquiry further, Dr. Cotgrove points out that, while the technical colleges contribute substantially to the supply of graduates in science and technology, only to a slight extent have the technical colleges acted in the post-war years as an overflow for the universities; at the time of the inquiry in 1955, not more than 20 per cent of the students in the sample were attending a technical college because they had been unable to secure a place at a university. Most had not even applied for such a place. Nevertheless, about a third of the full-time and one-half of the part-time students taking a national certificate course covered by the survey seem to prefer a university degree on the grounds of its prestige and greater educational and occupational value.

Dr. Cotgrove emphasizes the need to interpret this evidence with caution; but he is manifestly right in suggesting both that further inquiry is needed to show how far the pursuit of existing paper qualifications is meeting the educational needs of industry, and that more attention should be paid to the intermediate and technician level, which tends to be dominated by the training required for professional qualifications. The conduct of examinations is only one of the functions of a professional body; and although it is one way in which a professional association may serve social needs, it is one in which self-interest may easily lead to distortion and a tendency to safeguard sectional and professional interests rather than to serve public needs. There can be no question as to the public spirit which animates the educational policy of some professional bodies, but Dr. Cotgrove's survey also suggests some doubts as to whether in establishing a National Council for Technological Awards and the Diploma in Technology regard was being had, not so much to the needs of the students or of industry as to the supposed interests of the technical colleges themselves. Dr. Cotgrove makes no such comment, but his factual survey of what passes for policy in technical education relates very clearly the major problems to the conflicts of interest involved, and shows the way in which the original and primary functions of the technical colleges have been overlooked.

Those functions of training craftsmen and technicians in the principles underlying their trade can be met appropriately within the framework of local government administration. It is when this work is combined with that of training technologists that the growth of advanced courses requires concentration in selected areas and the recruitment of students from a wider area, with consequent problems of finance and arrangements outside the local authority area. The questions of prestige and of autonomy which result are liable to be debated subjectively rather than objectively, and such controversies have hampered the development of the technical colleges.

The value of Dr. Cotgrove's book does not lie in any positive contribution to the resolution of such controversies, but rather in indicating the factors to which weight must be given if our efforts to expand the supply of scientists and technologists, technicians and craftsmen are to succeed. Most technical colleges will continue their established role of concentrating on the training of technicians and craftsmen, though perhaps less exclusively on a part-time basis than Dr. Cotgrove implies; but the extent to which others concentrate on the training of technologists should be determined by considerations of man-power needs and resources rather than local or sectional prejudices or ambitions.

Further, more attention should be given to the influence of the social structure and to the educational system of Britain as a whole. Perhaps the outstanding lesson of the survey is that the system of further education must be conceived in relation to the structure of society if the demands for trained man-power are to be met. This involves some radical re-thinking of the relations between the various forms of secondary and further education, and equally a readiness to consider the impact of change on the various elements in the educational system. The apprenticeship system is scarcely mentioned in this study, but obviously has an important bearing, quantitative and qualitative, on the development of technical education. It is not the only point at which entrenched interests and the dead hand of tradition hinder adjustment of the educational system to changing needs of society.

If technical education is to meet the needs of Britain for trained man-power, there is no place for preconceived ideas. Dr. Cotgrove leaves no loophole for believing that any substantial increase in the output from the technical colleges is likely unless positive steps are taken to decrease the factors hindering recruitment. The White Paper on technical education proposed no such changes, and accordingly Dr. Cotgrove believes that any expansion is likely to result from the slow evolution of the system and the increase in the size of the age-groups from which students will be recruited during the next decade. Nor does he believe that the currently expressed needs of industry should dominate the nature of any educational re-organization. This, he urges, and rightly, should depend on much more detailed knowledge of the structure and functioning of the educational system and of the social forces which shape it. There is sound reason, while such knowledge is being sought, for avoiding fundamental change, and care should be taken to create no fresh obstacles to whatever changes or developments may appear necessary.

Such knowledge, however, and especially of the social consequences which are likely to result from educational policy, for example, the effect on social and industrial mobility, should be sought as a matter of urgency. When it is available, however, imaginative and constructive thinking will be no less imperative. To translate the results of such thought and knowledge into action will be a task demanding the co-operation of all concerned to see Britain take her full place in this age of technology; nor is it too early for professional associations as well as educational institutions to seek to promote such co-operation and to remove the misunderstandings and prejudices which are probably the greatest hazards to the formulation and execution of an adequate and effective policy of technical and technological education.

MOLLUSCAN DEVELOPMENT

Morphogenesis

The Analysis of Molluscan Development. By Prof. Chr. P. Raven. (International Series of Monographs on Pure and Applied Biology. Zoology Division, Vol. 2.) Pp. xii+311+12 plates. (London and New York: Pergamon Press, 1958.) 70*s*. net.

MODERN developments in experimental embryology may, as Prof. C. P. Raven notes in his introduction to this book, be reviewed in one of two ways. Certain problems may be concentrated on while drawing examples widely from the animal kingdom, or attention may be restricted to a single group, so permitting a survey of the normal course of development as the logical background to the causal analysis which is the aim of experimental studies. Prof. Raven has here chosen the latter course, dealing, as he is so highly qualified to do, with the Mollusca.

Indeed, this phylum offers an almost embarrassing wealth of material for description and analysis. Of its numerous marine representatives, some have larval development, but this may be abbreviated in many ways leading to direct development and even, in the Cephalopoda, to meroblastic discoidal cleavage. The freshwater Gastropoda and Lamellibranchia and the terrestrial Gastropoda exhibit other patterns of development including parasitic glochidia larvæ, ovo-viviparity and special adaptations in connexion with land life. They also present advantages to the investigator which Prof. Raven has fully utilized in his numerous studies on *Limnaea stagnalis*.

The book starts with an account of oogenesis, particularly valuable for its account of cytochemistry, followed by chapters on maturation and fertilization and on cleavage. Descriptive sections, dealing with structure in all its aspects, are followed by accounts, inevitably shorter, of work on causal analysis. The 'outfit' of the embryo is shown to consist of (1) its genotypical constitution, (2) an assortment of substances in the egg cytoplasm, and (3) a cortical field. The latter is considered not only to have a polar structure but also to be organized in dorsoventral and transverse directions.

The same course is followed in dealing with gastrulation and with embryogenesis, with the important distinction made between 'chemo-differentiation' in the embryo and the later 'chemical differentiation' which accompanies histological differentiation. The two, as the author emphasizes, represent opposite trends, one "functioning elements containing a great amount of fuel" and the other "formative cells, in which anabolism preponderates, leading to a synthesis of living protoplasm. . . ." It is interesting to note how, in the course of modern experimental attack, the old idea of mosaic development in the molluscan egg has been destroyed.

Criticisms are relatively minor. Some order might have been imposed on nomenclature when dealing with the excretory organs: larval kidneys include protonephridia, and these, on the evidence of different authors, are said to arise from either ectoderm or mesoderm. No reference is made to the work of Goodrich. The chapter on organogenesis is not altogether satisfactory. There are too few figures, making the unaided verbal descriptions most difficult to follow, for example, in the account of gill formation. There is also some apparent lack of knowledge of adult structure. "Inner and outer gill", meaning the inner and outer demibranchs of the bivalve ctenidium, is not satisfactory; supporting rods are always present within ctenidial filaments; the shell of a bivalve is a single structure with the ligament formed in the same manner as the valves. It does not appear to be realized that there is a fundamental difference between the asymmetry of the kidneys in the Archæogastropoda and in the remaining Gastropoda. There are also other matters which might suitably have been checked by a malacologist.

But it would not do to end on a note of criticism when dealing with a book for which many, including this reviewer, will long be grateful. Not only does it provide an admirable summary of the present state of knowledge in a difficult but most active field of research; it should be the means of stimulating further research. C. M. YONGE

HORMONES

Biochemical Contributions to Endocrinology

Experiments in Hormonal Research. By Sir Charles Dodds. (Stanford Studies in the Medical Sciences, No. 8. The Lane Medical Lectures, 1956.) Pp. viii+76. (Stanford, Calif.: Stanford University Press; London: Oxford University Press, 1957.) 18*s*. net.

IN this volume, which is based upon five Lane Medical Lectures delivered at Stanford University in 1956, Sir Charles Dodds recounts some of the biochemical research work in relation to endocrinology at the Courtauld Institute, Middlesex Hospital. Following a description of early work on insulin and posterior pituitary lobe factors, which is now only of historical interest, the author gives a fascinating account of the difficulties and uncertainties which beset his colleagues and himself in their search for synthetic compounds with œstrogenic activity. Isolation from urine of five different compounds with œstrogenic properties indicated clearly that, in this field at least, the contemporary belief that hormone specificity and structure were closely related was untenable. Such was the simple starting point of this inquiry, and rarely has persistent effort yielded such abundant reward. In stilbœstrol, hexœstrol and dienœstrol the target of cheap, highly active, oral, synthetic œstrogens was achieved, but perhaps the most significant outcome of this work has been the subsequent application of these powerful drugs. Apart from their use in menstrual disorders and weaning, Huggins was able to show that they had useful and possibly unique application in the treatment of carcinoma of the prostate and breast.

The use of synthetic œstrogens in cicuration to improve the quality of chicken and heifer meat has already great economic importance, but is not without potential danger to the animals, to those who handle the treated fodder and to the consumer of the meat. In the future, these compounds, or their derivatives, may find useful application in the control of lipid metabolism in atherosclerosis and allied conditions. It is well known that arterial degeneration is rare in women during active sex life and that the incidence of cardio-vascular disease in men and post-menopausal women with an associated disturbance of lipid metabolism is much higher. There is already some evidence that the abnormal plasma lipid pattern can be successfully treated by œstrogen therapy.

In bringing the brief story of the Courtauld Institute up to date, Sir Charles gives a concise account of the historical background which led to the discovery of aldosterone by Dr. Tait and his wife. Although at some pains to point out the advantages which may follow the association of workers of different disciplines, the author does not comment on the uniqueness of this combination of a radiation physicist and a biologist which resolved the difficulties of the amorphous fraction which had defeated chemists for a quarter of a century. The establishment of the constitution of aldosterone and its subsequent synthesis may have solved the chemical problems, but the important questions of physiological function and clinical use remain unanswered. That aldosterone influences the electrolyte balance is beyond doubt, but whether it does so primarily by action on sodium, potassium and chloride ion excretion in the renal tubules or indirectly by controlling the extra-cellular fluid volume by modification of the permeability of cell membranes is uncertain. Unlike other steroids synthesized in the adrenal cortex, the secretion of aldosterone does not seem to be under pituitary control. A. E. Kellie

FOSSIL VERTEBRATES

Studies on Fossil Vertebrates

Essays presented to David Meredith Seares Watson. Edited by Prof. T. Stanley Westoll. Pp. xii+263. (London: The Athlone Press, University of London, 1958.) Distributed by Constable and Co., Ltd., London. 35*s*. net.

This collection of essays deals with a variety of problems of prime interest to vertebrate palæontologists, some relating to the evolutionary history and comparative anatomy of extinct animals, others to the environmental conditions in which these animals lived, and the evidence offered in this respect by the fossiliferous rocks. In all these fields Prof. D. M. S. Watson has made lasting contributions, and it is highly proper, therefore, that the volume now published in his honour, should have this broad coverage.

Among the articles dealing with modern aspects of evolutionary theory, those entitled "Prophetic Fossils" and "Time and Evolution" are worthy of special mention. In the first, Sir Gavin de Beer and W. E. Swinton state the case, with many examples, of paedomorphosis versus recapitulation in the evolution of animals. In the second, J. Brough makes some critical and, as it seems, well-founded comments on the dynamics of evolution as interpreted by the neo-Darwinian school. Taking as an example the history of Actinopterygian fishes during Permo-Triassic times, Brough emphasizes that the transition from the Palæoniscoid to the Sub-Holostean, and afterwards the Holostean stage, which quite obviously took place independently within several different lines, can scarcely be attributed to conditions of small populations in connexion with environmental instability. In this case, as also with regard to the phyletic development of the jaw-apparatus in various mammal-like reptiles, the explanation rather seems to be that the evolution was non-adaptive, that it was influenced above all by variations in the mutation-rate, and that the mutations were, at times, not wholly random, but in some way directional. In such large-scale evolutionary outbursts where new orders, classes or phyla emerged, the causative factor was, so Brough maintains, probably an extremely high mutation-rate. Natural selection, on the other hand, may, in Brough's opinion, have been active as a guiding force in evolution, but only on a lower taxonomical level, for example, for the rise of new species, genera and to a large extent even families. Reviewing the phyletic history of animals from the early Cambrian onwards, Brough, in conclusion, tends to regard evolution as a decelerating process, in which large-scale surges all belong to the past, and which goes on at an ever-decreasing speed until, at some future date, it may cease altogether.

Three other articles in the volume have been written with the intention of summarizing and critically analysing the occurrences of fossil vertebrates in certain geological time-intervals or in certain specific areas. Valuable contributions of this kind are given by two American palæontologists: E. H. Colbert, who, in "The Beginning of the Age of Dinosaurs", presents a broad outline of the evolution of amphibians and reptiles during the critical Triassic period, and A. S. Romer, who, in a highly competent manner, deals with the Texas Permian Redbeds and their vertebrate fauna. E. S. Hills has contributed a brief review of Australian fossil vertebrates which, in condensed form, yields much up-to-date information on the rich finds, in that part of the world, of fishes and tetrapods in strata ranging from the Middle Devonian to the Late Tertiary.

The habitat of fossil lower vertebrates is the subject of two articles, "The Geological Environment of Fossil Fishes", by D. H. Rayner, and "Original Environment of the Craniates", by E. I. White. Miss Rayner has set herself the task of briefly evaluating to what extent such evidence as state of preservation, lithology of enclosing rocks, etc., may reflect the original environment of fossil fishes, giving, in this connexion, a rather detailed account of various fish-faunas from the British Jurassic. E. I. White, on the other hand, has chosen the more limited but highly controversial problem of fresh versus salt water as the habitat of the early vertebrates. After a careful consideration of the evidence, zoological and geological, White concludes that the earliest Craniates were wholly marine, and that the Ostracoderms lived off shore or in estuaries during pre-Devonian times. White successfully disposes of some of the irrelevant or untenable argumentation by which this problem has often been obscured. The frequently cited circumstance, for example, that in the early Devonian the Ostracoderms and fishes occur predominantly in continental sandstones, clearly proves nothing at all concerning the original habitat of the earliest vertebrates; and the view that the Ordovician and Silurian vertebrates belonged to inland waters, and that their detached exoskeletal plates and scales were washed out after death into the sea by rivers, is entirely unsupported by the facts as we know them. There may still be some diversity of opinion on certain of the aspects of early vertebrate history touched upon by White (for example, the successive phases in the phyletic development of the exoskeleton), but this by no means lessens the validity of his conclusions referred to above.

Finally, three articles deal with problems of palæoichthyology. F. R. Parrington and A. Heintz both discuss the anatomy and mode of life of the Anaspids, and in "The Lateral Fin-fold Theory and the Pectoral Fins of Ostracoderms and Early Fishes" T. S. Westoll, the editor of the volume, pursues an important problem of comparative anatomy. Interesting in many ways as they certainly are for specialists, none of these articles can be reviewed in detail here. It may be mentioned, however, that whereas Heintz in his description of *Birkenia* rejects the view that the Anaspids have a suctorial mouth, Parrington, who mostly considers *Lasanius*, strongly favours the opposite view. According to the latter, the Anaspids may, in their mode of feeding, have been intermediary to some extent between the Cephalaspids on one hand, and the modern lampreys on the other.

The volume of essays presented to Prof. Watson makes excellent and stimulating reading throughout. Its highly varied contents, to which no full justice can be done in a short review, should be of considerable interest to anyone working with vertebrate phylogeny. TOR ØRVIG

BIOLOGICAL TESTING OF INSECTICIDES IN THE LABORATORY

A Critical Review of the Techniques for Testing Insecticides

By Dr. J. R. Busvine. Pp. ix+208. (London: Commonwealth Institute of Entomology, 1957.) 30*s*.

IN the past ten or so years a number of rather similar books have appeared, each of them about the properties, uses and modes of action of insecticides. Dr. Busvine's book is the first to be entirely devoted to methods of testing insecticides; he is to be respected for his courage in tackling a subject with so many specialized subdivisions.

The book does not deal with methods for field tests, nor with chemical tests, but covers all types of laboratory biological tests. It is a review of a large subject, not just a collection of descriptions; it does not list all the methods that have been used for each type of test; and it does not give full details of more than a few. Dr. Busvine has concentrated rather on the principles and theories involved in tests, and on giving suitable guidance.

One of the praiseworthy aims of the book is to encourage greater simplicity and standardization of method. The subject is now well past its pioneering stage, and the methods used have been increasing in diversity and number. As the author says, research workers are "doggedly individualistic"; this has often made it difficult or even impossible to make comparisons among results obtained in different laboratories. There are enough uncontrollable sources of variation in any one type of test without individual workers adding variants of their own.

After three general chapters on principles, and on handling and standardization of insects, the author deals with each type of test, chapter by chapter.

However, there are quite a number of errors in detail, which give the impression that the book has been hurriedly prepared. In matters of theory and of interpretation of results, there are some more serious errors. These may not concern the routine tester, but may mislead research workers. For example, Dr. Busvine uses Ferguson's principle to explain the positive temperature coefficient of toxicity of hydrogen cyanide and the negative coefficient of toxicity of DDT. Ferguson specifically excluded hydrogen cyanide; and his principle can never offer more than a partial explanation for the temperature coefficient of DDT, which may sometimes, in fact, be positive.

There are some omissions. In the sections about humidity, there is no mention of saturation deficiency—a method for expressing humidity measurements with which many biologists are unfamiliar, and which could well be brought into a book like this. There is no general section about the various objective methods for telling whether or not an insect is affected by poison, or for assessing effectiveness in other ways; on the other hand, this question is quite fully dealt with in the section on tests with mosquito larvæ. This emphasis on tests with insects of medical importance is indeed a characteristic of the whole book.

The final chapter is about "Toxicological Statistics", or methods for planning tests and for assessing their results. It is refreshing to note that Dr. Busvine calls for moderate use of statistics when results are prepared for publication.

The lay-out of the book does not make for the greatest efficiency in use. There is no index. Instead, there is a systematically arranged table of contents, which is a list of some of the many headings that occur in the text. The material is classified and subclassified so much that there are ten different types of heading; as many as five of these may occur on one page, some of them often more than once. Many readers will find this irritating. In addition, some topics may be hard to find, because the material is not always logically set out. Thus, under "General Principles of Insecticide Testing" we find, besides some experimental detail, an account of the various aims that experimenters may have in mind when planning their tests; general principles are found under "Toxicological Statistics". The effects of temperature and humidity after treatment are described under "Standardisation of Insects for Testing". Probits are mentioned casually from place to place in the body of the book, but are not defined until well into the last chapter.

This book is not perfect, but it should be useful all the same, especially as it is the first of its kind. There are more than 550 references, covering all the important branches of the subject. A. H. MCINTOSH

GENERAL ENTOMOLOGY

A General Textbook of Entomology

Including the Anatomy, Physiology, Development and Classification of Insects. By A. D. Imms. Ninth edition, entirely revised by Prof. O. W. Richards and R. G. Davies. Pp. x+886. (London: Methuen and Co., Ltd., 1957.) 75*s*. net.

WHEN in 1925 A. D. Imms published his "General Textbook of Entomology" it at once became clear that here was a synthesis of a major field of zoology which was likely to prove to be an outstanding work in its sphere for at least half a century. The third revised enlarged edition of 1934 served to maintain the value and prestige of the work, but the subsequent so-called editions, from the fourth (1938) to the eighth (1951), were mere reprints and the book has thus been falling far behind as the already great development of the subject increased in momentum over the years. The publication, therefore, of a ninth edition is of great value, and it can be said that the authors have done a difficult job outstandingly well. It is scarcely possible, even if it were desirable, to attempt a minute critique of a work containing such an immense amount of detail; for the great merit of Imms's text-book was the masterly way in which he condensed an enormous amount of information into a relatively short space (750 pages) with a wonderful flair for retaining what is really important.

In the new edition the original format and layout have been retained and we are obviously dealing with 'the same book'. But it has been enlarged by nearly 200 pages, on almost every one of which there seems to be some significant change. As the editors point out, about 4,000 papers and books on insects now appear annually, and such an output from the production line does indeed set an almost impossible task to would-be summarizers. Obviously much must be left out. The editors have made their selection with sound judgment. They could, of course, have cut out the physiological side entirely and thus greatly eased their task. It would, I think, have been a great pity to have done this, and although the physiological chapters cannot be, from the nature of the case, as full and thorough as the rest, to have left them out would have so changed the nature of the book as to deprive it of one, at least, of its great merits. Quite apart from the great and steady increase in the quantity of publications on the insects, the task involved as a result of the mere increase in the number of described species is almost overwhelming. Perhaps we get the best idea of this increase if we compare two of the main groups. In 1925 the text-book writer was concerned with 50,000 species of Diptera, comprising 45 families. He now has to deal with 64,000 species classified into 83 families. In the Hymenoptera the classification has not been extended very much although the described species have risen from 60,000 to 100,000. All this has, of course, to be expressed in the general classification.

The original "Imms" classified the Insecta into 23 orders, grouped in two sub-classes. R. Jeannel in Grassé's recent text-book adopts a modified Martynov classification of 40 recent orders comprised in two sub-classes and 15 super orders. Brues and Melander (1932) had 34 orders against Imms's original 25. Prof. Richards, in the new edition of "Imms", has been very conservative in this. He considers that while many of the new divisions adopted by Handlirsch (1908), Martynov (1938) and others are probably justified and certainly desirable in attempting to incorporate the much greater knowledge of fossil insects that we now have, many of the innovations are of doubtful success; so although a number of the changes are, in principle, approved and receive critical discussion, the layout of the scheme of classification has not been very greatly changed. The general student is at least spared the task of having to remember 35 or so recent orders, being let off with 29.

Among the sections in the latest edition which can be regarded as mainly new are the general ones on classification, sections of those on the musculature, physiology of the nervous system, sense organs and perception and on digestion. The section on the physiology of respiration does not seem to have quite kept pace with some of the rest; and neither the account of the air sacs nor that of the mode of action of the closed tracheal system is quite as clear and precise as would now be possible and as might have been expected. However, there is a good new account of the blood and blood system and an excellent short summary of the present state of knowledge on endocrines.

Perhaps the most important new feature of the book is the large number of new and important keys which it provides. Almost all the main orders have received some new treatment in this respect and particularly outstanding are the new keys to the Diptera, the Hymenoptera and the Coleoptera, the last being largely based on the work of Crowson. There is no doubt at all that the keys to these three main orders have been enormously improved. The increase in the number of illustrations has not kept pace with that of the text; in fact the new edition has somewhat fewer than the old. This is, perhaps, rather a pity and it would seem that more of the old figures might have been discarded for new ones. Where changes have been made, however, they seem to be excellent and in particular some of the new illustrations of the external morphology of the Hymenoptera will be very useful. Considering the book as a whole there is no doubt that it is an eminently worthy revision of a really outstanding text-book, and not much higher praise than that can be given. It should, with enough subsequent less intensive revisions, enable the work to retain its place in the forefront for many years.

W. H. THORPE

EASTER ISLAND CULTURE

Aku-Aku

The Secret of Easter Island. By Thor Heyerdahl. Pp. 368+37 plates. (London: George Allen and Unwin, Ltd., 1958.) 21*s*. net.

EIGHT years after Thor Heyerdahl made his epic voyage on the *Kon Tiki* raft, he returned to Polynesia with an archæological expedition to undertake a study of Easter Island culture. The initial results are given in this vividly written and finely illustrated book. As well as accumulating a great deal of general information about Easter Island culture, the expedition performed two very important services. Some of its members engaged in much more extensive scientific excavation than any earlier visitors had done, while Heyerdahl himself discovered a series of family caves with curiously carved stone figures of novel type.

The book sets out to show that the secret of Easter Island, including the 'mystery' of how its giant statues came to be, has now been solved. But the anthropological reader may well feel that the author, in solving some problems, has only created some new ones. It is good to have the actual proof by word and photograph of how these enormous statues can have been hauled along the ground by ropes and raised by wooden levers on stone ramps to their upright position. But this is confirmation rather than discovery of method. Métraux, in 1934, was told of the embankments and ramps by means of which the statues were brought to the level of the platform on which they would be placed, and also of wooden levers, crushed potatoes and round stones which helped these heavy masses to slide along. Even in 1914 Mrs. Routledge had found behind some statues the mounds of stones which had supported them while they were being raised into a vertical position. But Heyerdahl's organizing gift of enlisting enthusiastic co-operation has now given us a practical demonstration.

The weights involved still remain somewhat obscure. Heyerdahl speaks of 180 people pulling a statue of 12 tons and of twelve men raising a statue weighing between 25 and 30 tons. He also talks of one, of which the density and measurements were obtained, weighing 50 tons. Métraux, taking the density of the volcanic tufa as 2.48, as measured in the Laboratory of Geology, Paris, calculated that statues of this material which were actually transported weighed only 5–6 tons, although others still at the site of manufacture were as much as five times that weight. Heyerdahl is critical of the estimates of his predecessors and speaks of the rock as very hard ("hard as bone inside the outer surface"), but gives us no precise data from which comparative estimates can be checked.

The stone figures from the caves raise questions only meticulous study can answer. By a combination of friendliness, gifts, ingenious bluff and playing on the Easter Islanders' notions of spirits, Heyerdahl obtained access to a number of caves, the secret of which appears to have been most carefully guarded from previous investigators. He is to be congratulated on a magnificent feat of persistent inquiry and discovery. But the results of this exciting story as yet are still rather puzzling. These extraordinary figures, which all seem quite small, include bearded heads, stone skulls, a three-masted 'reed boat', a whale with a house on its back, a woman with a fish roped to her shoulders. Who made them ? From the photographs and description some appear to be ancient specimens. Others look like relatively modern work. Heyerdahl himself says that some stone figures were ancient, that some were made by the father and the grandfather of the woman from whom he received them, that some other figures, allegedly from the caves, were made as fakes to sell to him and treated to look old, and that the 'mayor' of the island, a superb carver, rigged up a complete cave of bogus figures in an attempt to hoax him. Out of this medley, selection of the genuine traditional specimens cannot have been simple. Moreover, we are still almost without a clue as to their meaning.

The book concludes with a restatement of the author's contentions as to the American origin of Polynesian culture—arguments based so far on very debatable evidence. We therefore await with interest the detailed analysis of the expedition's archæological findings. RAYMOND FIRTH

THE YEASTS

The Chemistry and Biology of Yeasts

Edited by A. H. Cook. Pp. xii+763. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 22 dollars.

YEASTS have been studied for many years because of their importance in fermentation industries, and this has led to the building up of a large amount of miscellaneous information, most of it directly related to industrial practice, but including also many studies of more general application. More recently, interest in yeasts has intensified and much work of a fundamental nature has been done on the biology and biochemistry of these organisms. The time is therefore opportune for an authoritative and comprehensive survey of what is known about yeasts. The book under review has this as its aim and it hits the target very near the bull's eye. Perhaps the best idea of the scope and standard of the work may be conveyed by a list of the subjects treated, with their authors' names: yeast classification (J. Lodder, W. Ch. Slooff and N. J. W. Kreger-van-Rij), ecology (A. Lund), life-history and cytology (Ö. Winge and C. Roberts), genetics (Ö. Winge and C. Roberts), chemical composition (A. A. Eddy), growth (E. O. Morris), fermentation and respiration (F. F. Nord and S. Weiss), synthesis and degradation of cellular carbohydrates (W. E. Trevelyan), nitrogen metabolism (G. Harris), technology (Magnus Pyke), pathogenicity (G. C. Ainsworth), food spoilage activities (M. Ingram), and flocculation (H. E. Jansen). The success or failure of a collection of individual articles such as this, however, depends not only on the contributors, but also to a large extent on the editor. In this case, the editor, A. H. Cook, has obtained admirable results; his team of authors is well balanced and includes some with a world-wide reputation; these authors have obviously been well coached so that there is a reasonable uniformity of style; their areas of activity have been adequately defined so that while the field is well covered there is little unnecessary overlapping, and their articles all come up to a very high standard of freedom from linguistic errors and misprints.

It is not possible to comment on each article individually within the space of a short review, but in many ways they are remarkably similar. Each article surveys the present state of knowledge in a particular field, with special attention to work published within the past few years; it is subdivided under headings, sub-headings, and in some cases sub-sub-headings; it is well illustrated with figures and tables and is followed by an alphabetical list of references, which in every case includes literature up to 1956 or 1957. There are some outstanding articles by authors who, while contributing largely to the field they review, have been able to give an objective view of the subject as a whole; these are authoritative and critical surveys of great value. Other articles do not quite come up to this high standard. The articles are followed by an author index (containing about 2,500 names) and a subject index (69 pages). Altogether, the book is by far the best available statement of our present knowledge of yeasts.

I should have liked fuller discussion of adaptation, autolysis, sulphur metabolism, the Pasteur effect and of the formation of esters and other secondary products of fermentation, but there would be difficulty in deciding what to leave out in order to make space for this new material. In the author index I found almost every name which came to mind, but in the subject-index under the letter 'A' I failed to find acetal, acetyl methyl carbinol, actidione, adaptation, adaptive enzymes, aeration, amyl alcohol or azide; no mention of the first three of these was found in the text, but the remainder are mentioned in the text and some are indexed under other headings (enzymes adaptive, *iso*-amyl alcohol and sodium azide); this indicates that the cross-referencing might be improved. Other changes that could be recommended are that footnotes should be eliminated, and that the magnification should be indicated on the photomicrographs where it is missing. One other criticism which might be made is that the price is high; but the paper, printing and binding of the book are of the highest quality and, if this is the cost of producing such a book, then we must pay it, because we would not wish for any lowering of the standard of production and because access to this book is a necessity for everyone who is working with yeasts. R. B. GILLILAND

PERGAMON PRESS

New and forthcoming titles

These volumes are published for the Advisory Group for Aeronautical Research and Development of the North Atlantic Treaty Organization.

OPERATIONAL RESEARCH IN PRACTICE

Edited by **MAX DAVIES** *and* **MICHEL VERHULST.**

The foreword by General Norstad reads:

" Operational research, by revealing methods for more effective utilisation of our manpower, our skills, our material, and our resources, is making a significant contribution to the military potential of the Atlantic Alliance. This is of utmost importance, for our strength depends not alone on what we have but to a large extent on what we do with what we have.

" I am gratified, also, by the promise these new techniques offer for application in non-military fields. They should serve to stimulate and strengthen the economics of the NATO nations."

Lauris Norstad, Gen., U.S.A.F., Supreme Allied Commander, Europe.

HIGH TEMPERATURE EFFECTS IN AIRCRAFT STRUCTURES

Edited by **NICHOLAS JOHN HOFF.**

The development of supersonic airplanes and missiles has rendered obsolete most of the knowledge of the old-timer in aerodynamics and is now beginning to play havoc with the traditional information acquired by the structural designer and analyst.

It was decided that the dissemination of information on structural effects of high temperatures caused by aerodynamic heating could best be accomplished by persuading outstanding scientists and engineers to survey a number of distinct portions of the subject and to write review articles to be incorporated in the book as individual chapters. This volume includes new and unpublished results as well as summaries of available information.

AVIATION MEDICINE

Edited by **W. RANDOLPH LOVELACE II, CLAYTON S. WHITE,** *and* **F. G. HIRSCH.**

In the course of work assessing recent advances in instrumentation and related methodology of interest in aviation medicine, twelve reports were prepared by senior aeromedical scientists. AVIATION MEDICINE assembles these papers in a volume representing the present state of knowledge.

The approach is that of a selective and critical review of areas of aeromedical science, and over 700 references are cited. This condensation of material allows the research workers to scan broad areas.

VACUUM GAUGES

we have progressed since *McLeod*

it is now **Kammerer**

The new Kammerer Vacuum Gauge applies the same principle as the McLeod Vacuum Gauge, but it has been designed in accordance with modern engineering methods giving the following advantages.

★ Small, handy apparatus ★ Lowest possible mercury filling
★ Facilitates easy and quick measurement

For further information regarding this equipment, please send your enquiries to Leybold Vacuum Sales, Ltd., Dept. N.P.

Annual Review of Nuclear Science

Vol. 7. Edited by James G. Beckerley, in association with Robert Hofstadter and Leonard I. Schiff. Pp. viii+496. (Palo Alto, Calif.: Annual Reviews, Inc., 1957. Published in co-operation with the National Research Council of the National Academy of Sciences.) 7 dollars.

VOLUME 7 of the "Annual Reviews of Nuclear Science" contains the following twelve contributions: Mu-Meson Physics, J. Rainwater; Radiochemical Separations by Ion Exchange, K. A. Kraus and F. Nelson; Equipment for High Level Radiochemical Processes, N. B. Garden and E. Nielsen; Cellular Radiobiology, E. L. Powers; Biochemical Effects of Ionizing Radiation, B. E. Holmes; Vertebrate Radiobiology (Lethal Actions and Associated Effects), V. P. Bond and J. S. Robertson; Vertebrate Radiobiology (The Pathology of Radiation Exposure), C. C. Lushbaugh; The Collective Model of Nuclei, F. Villars; Nuclear and Nucleon Scattering of High-Energy Electrons, R. Hofstadter; Collision of $\lesssim 1$ BeV. Particles (excluding Electrons and Photons) with Nuclei, S. J. Lindenbaum; The Measurement of the Nuclear Spins and Static Moments of Radioactive Isotopes, W. A. Nierenberg; Hyperons and Heavy Mesons (Systematics and Decay), M. Gell-Mann and A. H. Rosenfeld.

The articles in this volume are up to the very high standard which we have come to expect in this series. Most of them represent excellent up-to-date surveys which, in different ways, should be equally valuable to the expert or the new research student who wants a readable introduction to a new field and is overwhelmed by the published literature. The review by Rainwater and, to a much lesser extent, that by Gell-Mann and Rosenfeld were written at an inopportune time. They were concluded within a few months of the discovery of parity violation in weak interactions, when these subjects were in a state of violent change. As a result, much experimental work done since their completion is missing from these surveys and theoretical conjectures based on conflicting or sparse data would be on sounder foundation to-day.

It would seem most desirable to be able to buy individual articles (friends of authors may already be lucky enough to receive such complimentary copies) at a small fraction of the present price.

F. MANDL

Nuclear Chemical Engineering

By Prof. Manson Benedict and Prof. Thomas H. Pigford. (McGraw-Hill Series in Nuclear Engineering.) Pp. xiv+594. (London: McGraw-Hill Publishing Company, Ltd., 1957.) 71*s*. 6*d*.

A WIDE interpretation of the title is possible, but the authors have made it clear that they are concerned with the materials of importance in nuclear reactors and the novel processes which have been developed to concentrate, purify, and separate them. The use of nuclear radiations in processing materials is not dealt with.

The strength of the book lies in its very thorough theoretical treatment of the various flow sheets which have either been developed or grown in importance as a result of the growth of nuclear power. On this subject the reader will expect much from two such distinguished authors, and he will not be disappointed.

The thermal nuclear reactor is treated simply as a chemical engineering process and, rightly, no attempt has been made to summarize the theory of nuclear reactors. Fuel flow sheets are developed for a typical reactor. Although the principles are well presented, a more critical review of the effects of the assumptions on the results would be welcomed.

Two chapters deal with the production and properties of uranium, zirconium, thorium and beryllium, but no mention is made of graphite. There is an excellent description of solvent extraction processes.

The chemical and radioactive properties of irradiated fuel receive adequate treatment, as does the separation of reactor products. A very thorough and well-written account of the theory of isotope separation and applications is given.

The production is good except for the poor photographs. The authors' wide experience of industry and university has resulted in the production of a first-class book which is highly recommended.

W. MURGATROYD

Progress in Biophysics and Biophysical Chemistry

Vol. 8. Edited by Prof. J. A. V. Butler and Prof. B. Katz. (Progress Series.) Pp. viii+409. (London and New York: Pergamon Press, 1957.) 105*s*. net.

THIS volume has four articles on various aspects of protein synthesis and the nucleic acids, and five others on hearing, colour vision, bacterial electrochemistry, the nerve axon and red cell permeability. No doubt they will all be of value, and some will certainly be of great value, to specialists in these fields. But it is not to this clientele that the editors say they address themselves. They aim higher and "believe that collections of critical reviews of this kind will help to provide a meeting ground for all those scientists who, in spite of their very different methods of approach, are concerned with the applications of physical principles to biology".

In judging their success it must not be forgotten that the scientific reader out to widen his acquaintance is an extremely shy person. In a good deal of the book, unfortunately, the approach is not likely to charm his hesitancy. We can scarcely blame the editors for this, for it is notoriously difficult to extract from the expert a critical account of the fundamental facts and ideas current in his subject, and to get it written in sufficiently attractive and explicit language to be interesting and intelligible to his scientific neighbours. Rather we must be grateful to them, and count their book a success, for the two or three outstanding articles it contains which do possess the rare qualities needed to make friends and influence people.

P. A. MERTON

An Introduction to Probability Theory and Its Applications

Vol. 1. By Prof. William Feller. Second edition. (Wiley Publications in Statistics.) Pp. xv+461. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 86*s*. net.

THIS, the second edition of Prof. Feller's well-known book, contains a new chapter on "Fluctuations in Coin Tossing and Random Walks", and in it results obtained earlier by advanced methods are now deduced by elementary means. Throughout the book there is increased emphasis on waiting times.

There is a rather remarkable aspect of duality pervading the account. The theory of probability is developed with a degree of rigour which should satisfy the pure mathematician. But there are also applications to practical situations, including the estimation of the size of an animal population, the distribution of misprints in a book, or of raisins in a cake, or of flaws in a material; and the exposition is made the more colourful by reference to card games, birthdays and the spread of rumours.

The later chapters include one on random walk and ruin, and several covering Markov chains, recurrent events and time-dependent stochastic processes. These topics, apart from their current interest to research workers, have important applications in the study of industrial operations, and an example of the latter is the subject of machine interference, an aspect of which is treated on pp. 416–422.

The book is very well produced and only one error has been noticed. On p. 164, x^2 not x should appear in the definition of $\varphi(x)$; the same mistake occurs on p. 166. The title page still describes the work as Volume 1. But it is generally known that Volume 2 has not appeared, and it is believed that it will not appear. On the other hand, on p. 173 it is still stated that a certain matter "must be postponed to the second Volume". Thus, an enigma still surrounds the present work, and it would be good if the publishers could clarify the position.

L. S. GODDARD

The Birds of the British Isles

By Dr. David Armitage Bannerman. Vol. 7: Anatidae (Conclusion). Pp. x+256+27 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1958.) 63*s*. net.

DR. BANNERMAN'S seventh volume covers the dabbling and diving ducks, including the sawbills. He has been able to draw upon even richer material than usual, as the ducks have always been special favourites of some ornithological writers, such as J. G. Millais; they are also well known to sportsmen, who have added to the store of information—especially about habits in winter-quarters in Africa and southern Asia. In our own day and country, too, wildfowl have been the subject of special inquiries into their numbers and habits; not least interesting is the increase, within living memory, of the British breeding populations of several species formerly scarce at that season. Yet again, ducks can be caught for ringing not only when young but also in decoys in winter; and they yield a good proportion of recovery records. Thus, for example, the author is able to quote descriptions of breeding harlequin (a remarkably rare visitor to us) in Iceland and of wintering garganey (one of our less common summer birds) on an equatorial lagoon; and he can cite records of ducks ringed in Britain that have travelled far into the U.S.S.R. The late George Lodge had likewise fine scope for his art in depicting the many distinctively plumaged drakes, contrasted with their relatively sombre mates; one would have liked some of the ducklings as well.

LANDSBOROUGH THOMSON

Natural Selection and Heredity

By P. M. Sheppard. Pp. 212. (London: Hutchinson and Co. (Publishers), Ltd., 1958.) 18*s*. net.

IF this book had been entitled "Natural Selection and Mendelian Heredity" with a sub-title *à la* Darwin, "Or an account of Speciation according to neo-Mendelian Principles", and had stopped at the end of Chapter 8, it could be called a good book. It is clearly written; at least, as clearly as the intricacies of the neoMendelian hypothesis will allow. But it is not certain for whom it was written. In some places it explains matter with a simplicity which is almost childish (p. 116), while at others it demands a mind of marked mathematical acuity to follow the argument (p. 107).

However, after having devoted eight chapters—just two-thirds of the book—to the "agents" which "control speciation", the author deals with protective coloration (for some reason which is obscure), with mimicry where one hoped for some modern enlightenment on this intricate problem, with a chapter of six pages on ecological genetics, and then, *mirabile dictu*, a chapter entitled "The Origin of Species". After all this there is a conclusion where it is naïvely stated that all the evidence (dealt with so superficially in the last four chapters) supports the idea that the major advances in evolution, the origin of orders, classes and phyla, are controlled by a mechanism "in no way different" from the neoMendelian tortuosities described at such length in the earlier part of the book. The fact that nowhere in the book is the origin of a new structure dealt with is overlooked. Since all the major steps in the evolutionary scale involve the appearance of entirely new structures, this surely detracts from the value of the argument. However, does this matter? The author admits the possibility of cytoplasmic inheritance (p. 171), and throughout the book deals with environmental variation (p. 63), and this, coupled with the recent statement by one of our leading neoMendelians in a review of three books, whose authors have had the temerity to write on evolution, that, of course, "the nucleus is not alone responsible for heredity", makes one wonder whether the present book has anything more than a purely hypothetical interest.

H. GRAHAM CANNON

Sixth Symposium (International) on Combustion

Yale University, New Haven, Connecticut, August 19–24, 1956. Pp. xxv+943. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1957. Published for The Combustion Institute.) 224*s*.

THIS weighty volume contains 125 original papers, of which six are invited surveys and most of the rest report original work, either theoretical or experimental. Group subjects include laminar and turbulent flame propagation, fast reactions and fast flame stabilization, combustion chamber instability, ignition, combustion of liquid and solid fuels and of explosives, techniques and applications.

The publishers' work has been excellently done, but one could wish that the editors had insisted upon the provision of abstracts uniform in location and style. Many of the papers lack this feature entirely.

The meagre discussion is incompletely reported. It is scarcely fair to record critics' comments and not the authors' replies. The reverse is disconcerting. If this is the best that can be done, the space had better be saved. Reports of three panel discussions are of more interest, especially the first and most substantial on "Future Problems in Combustion Research".

Some of the papers are unsatisfactory in that the date of the Symposium rather than the state of the work has rather obviously been the factor determining publication. Despite any or all such criticisms, however, the book contains a wealth of material that will probably justify the high price in the eyes of the many workers in the field of combustion.

J. H. BURGOYNE

AN EXPERIMENTAL SOLUTION TO THE PARADOX OF DISCONTINUOUS RESPIRATION IN INSECTS

By ROBERT I. LEVY and Dr. HOWARD A. SCHNEIDERMAN
Department of Zoology, Cornell University, Ithaca, New York

IN pupæ of the Cecropia silkworm, *Hyalophora cecropia*, as in many other insects, most of the metabolic carbon dioxide is retained within the insect and released in bursts during brief periods when the spiracles are widely open, which may occur only three or four times each day[1]. Shortly after the burst of carbon dioxide, the valve at the opening of each spiracle flutters for a few moments and then constricts almost completely, remaining motionless for as long as an hour. Following this silent period, the valve begins to pulse and then flutter faintly, slightly enlarging the spiracular opening. Fluttering continues, often for several hours, until the next period of wide opening and release of carbon dioxide. Between bursts, only a trace of carbon dioxide escapes. Notwithstanding this cyclical behaviour of the spiracular valves and the resulting discontinuous release of carbon dioxide, the oxygen uptake of the pupa appears almost continuous[2]. We are thus faced with the perplexing fact that oxygen enters the pupæ during the interburst period at 6–100 times the rate at which carbon dioxide leaves. How can the spiracles, which are the sole site of gas exchange[2], allow oxygen to enter, but effectively bar the release of carbon dioxide ?

During the past five years, numerous explanations have been offered for the disparate rates of gas exchange[3]. We have even imagined a 'Maxwell's demon' at the entrance of each spiracle, which lets in oxygen but holds back carbon dioxide. Buck[4] has recently claimed that the disparate rates of interburst oxygen and carbon dioxide exchange are inexplicable on the basis of simple physical diffusion. He proposes that a partial vacuum develops within the tracheal system after spiracular constriction because oxygen is taken up faster by the tissues than carbon dioxide is given up. The possibility of such a vacuum developing within the tracheal system of an insect was first pointed out by Wigglesworth and Herford[5], who noted that the tracheal system of fleas collapsed rhythmically because of a negative barometric pressure within it. In the case of the silkworm pupa, Buck argues that the air inflow caused by the suction impedes the diffusive escape of carbon dioxide from the tracheal system. This attractive theory is unsupported by direct measurements of gas concentrations in the tracheæ (in fact, no true measurements of this sort exist), or by measurements of the time course of the supposed gas changes. To provide this information and to test the theory, we have developed techniques for measuring the composition of the gas in the pupal tracheal system during the respiratory cycle. The present article describes briefly how such measurements were accomplished and provides the first direct and repeated measurements of the composition of the tracheal gas of an insect. The measurements confirm the theory and thus resolve the paradox of discontinuous respiration.

Glass cannulæ were inserted into one or more of the fourteen spiracles of the insect to a point just beyond the spiracular valve, sealed in place with paraffin and filled with mercury. Cannulated pupæ continued to give bursts of carbon dioxide. A fine pipette was inserted into the cannula through the mercury seal and into the tracheal manifold (Fig. 1), and 0·5 mm.^{3} of gas was withdrawn from the tracheal system at intervals of 10–45 min. over periods as long as 24 hr.; the gas was analysed for oxygen and carbon dioxide with the micro-gas-analyser of Scholander[6]. Nearly one thousand such samples were obtained from about twenty *Hyalophora* pupæ, and their analyses (accurate to 0·3 per cent) revealed striking cyclical changes in the tracheal tensions of carbon dioxide and oxygen that corresponded to the cycle of carbon dioxide bursts.

The overall gas exchange of a pupa with a typical cycle of about 1 hr. duration was measured manometrically in a Warburg apparatus and is recorded in Fig. 2*A*. Tracheal gas analysis was carried out on the same pupa less than 2 hr. after the Warburg record was made. The results, Fig. 2*B*, reveal cyclical changes in tracheal carbon dioxide and oxygen tensions corresponding to the gas exchange results recorded manometrically. Gas analysis results for another pupa are presented in Fig. 3, which also reveals striking cyclical changes in the tensions of the tracheal gas.

Similar results were obtained from other pupæ, and it is clear that the cyclical changes in gas tension may conveniently be divided into three phases : (1) a period during which oxygen tension rises sharply and carbon dioxide tension falls, which we term the 'burst'; (2) a period during which oxygen tension falls steadily and the carbon dioxide tension slowly rises, which we call the 'oxygen fall period'; (3) a

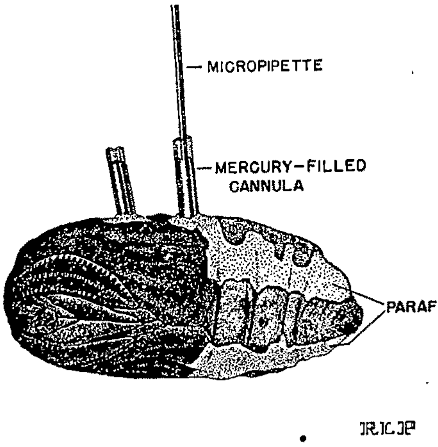

Fig. 1. Micropipette entering tracheal system of a *Hyalophora* pupa through mercury-sealed glass cannula in third abdominal spiracle. The pipette is about 0·3 mm. in diameter

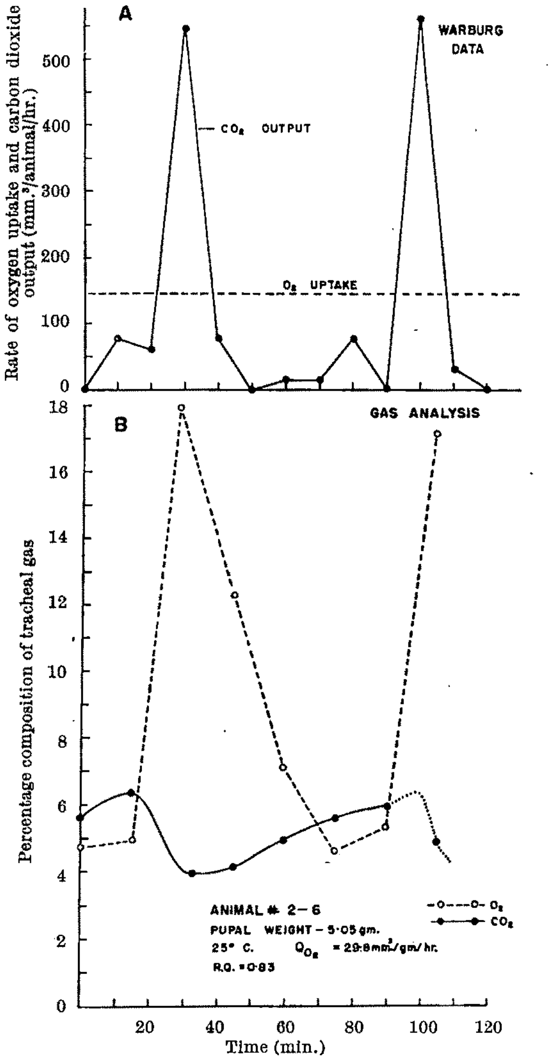

Fig. 2 (*A*) Warburg record of oxygen uptake and carbon dioxide output of a pupa. The cycles of carbon dioxide 'bursts' are clearly evident
(*B*) Record of changes in the tracheal gas tensions of the same pupa during the carbon dioxide 'burst' cycle. The two records have been given the same time axis to emphasize their correlation

period which we term the 'level oxygen period', during which oxygen tension, after suddenly ceasing its steady fall, levels off and remains fairly constant, while the carbon dioxide tension continues its slow increase.

Simultaneous records of movements of the spiracular valve and composition of tracheal gas suggest the following explanation for these cyclical changes in the latter. When the spiracular valve opens widely, carbon dioxide, which has accumulated internally, diffuses out of the tracheal system through the spiracle. Simultaneously, atmospheric air diffuses into the tracheal system, almost equilibrating the internal and the external oxygen tensions. The valve, after remaining open for a time, flutters and then constricts and lies still. With the valve in its constricted position the spiracular aperture is so small that it impedes the diffusive entry of oxygen and, as the pupal tissues respire, oxygen tension within the tracheal system drops sharply, and the tensions of carbon dioxide and nitrogen rise. Finally, oxygen tension falls to a critical threshold, which for most pupæ at 25° C. is about 3·6 per cent, and this initiates valve fluttering. This fluttering lets in enough oxygen to level off and even cause a slight rise in the internal oxygen tension. The fluttering also allows some carbon dioxide and nitrogen to escape from the tracheal system, thereby causing a levelling or slight drop in internal nitrogen tension and an almost imperceptible decrease in the rate of accumulation of carbon dioxide. During the periods of valve closure and fluttering, the internal carbon dioxide tension rises slowly and steadily from 3 per cent to about 6·4 per cent, the slowness being a consequence of the buffering action of the blood. Finally, when carbon dioxide tension in the blood and tissues (which are in equilibrium with the tracheal carbon dioxide) reaches a critical threshold, the valve opens widely, carbon dioxide diffuses out in a burst, air rushes in and the cycle begins again.

Thus the spiracular valve exhibits two distinct kinds of response to two different stimuli. Low oxygen tension causes partial, graded, relaxation of the spiracular muscle and fluttering of the valve. High carbon dioxide tension produces an all-or-none response: muscle relaxation and wide opening of the valve. Our results persuade us that, contrary to apparent doubts[7], fluttering is a normal response of the spiracle and is triggered off by oxygen tension.

This control of fluttering by oxygen tension is shown dramatically in records of valve movements at varying oxygen tensions. Oxygen tensions greater than about 50 per cent eliminate fluttering entirely and leave only the all-or-none response to carbon dioxide[1]. If the level-oxygen period is, in fact, a consequence of fluttering, as we suggest, one would anticipate that since no valve fluttering occurs in pupæ exposed to high oxygen tensions, analysis of tracheal gas would fail to reveal a level-oxygen period. This prediction is borne out in the results presented in Fig. 4, which describes the changes in composition of tracheal gases of a pupa maintained in 59 per cent oxygen. The period of decrease in oxygen tension is greatly lengthened and the level oxygen period disappears entirely. Apparently with high external oxygen tension, the tracheal oxygen tension never falls low enough to trigger off the fluttering responsible for the level-oxygen period. This result re-emphasizes that the spiracular mechanism is sensitive to lack of oxygen as well as to accumulation of carbon dioxide[8].

The present experiments provide one final piece of information. They give direct experimental support for Buck's theoretical explanation of the paradoxical disparate rates of gas exchange during the interburst period[4]. Employing the most extreme values found in our analysis of tracheal gases for the gradients for diffusive entry of oxygen and exit of carbon dioxide, a simple calculation using Fick's law of diffusion shows that these gradients would permit at most a five-fold difference in transfer-rates of diffusion. Hence we are forced to conclude that simple diffusion alone cannot account for the gas exchange of the pupa during the interburst. This conclusion, although it contradicts our usual ideas about insect respiration, is inescapable. Something other than the simple thermal agitation of molecules is responsible for driving oxygen into the insect at up to a hundred times the rate at which carbon dioxide leaves. The answer is apparently this.

When the spiracles close at the end of a burst, oxygen is used up faster than it enters, and the tracheal oxygen tensions falls. That is, the spiracular

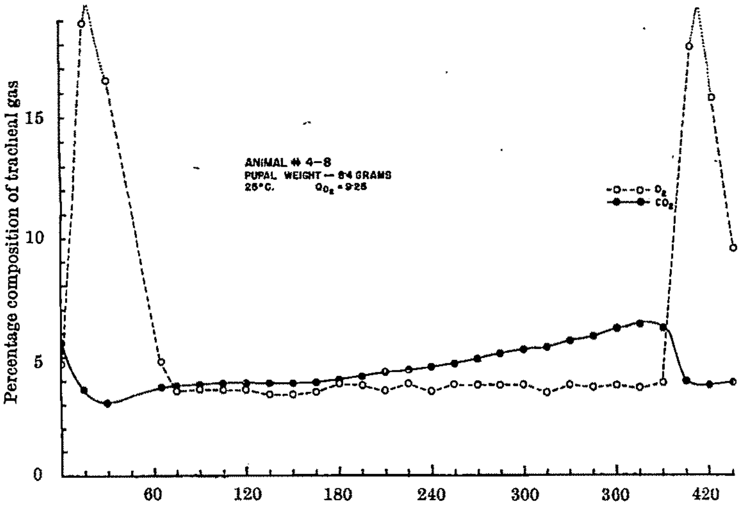

Fig. 3. Record of changes in the tracheal gas tensions of a pupa with a long carbon dioxide 'burst' cycle

openings are so small during this period of falling oxygen tension that they limit the inward diffusion of oxygen. Since a large proportion of the carbon dioxide molecules produced is dissolved and buffered by the blood, for every five molecules of oxygen used perhaps only one carbon dioxide molecule enters the tracheal gas space. This means that gradually the total number of gas molecules within the tracheal system decreases and the internal barometric pressure gradually falls. In other words, the absolute pressure within the tracheal system falls below atmospheric as the result of oxygen utilization. The consequences of this difference in pressure are tremendous. It means that through the tiny spiracular opening a stream of air will flow into the tracheal system following, not a diffusion gradient which depends on partial pressures, but a gradient of absolute pressure. In effect, the insect maintains in the tracheal system, a partial vacuum and sucks in air molecules. This mass inflow of air will not only bring in oxygen but also impede the outward diffusion of carbon dioxide and lead to a build-up of this gas within the insect that will persist as long as the spiracular opening is kept small. Nitrogen will also accumulate, since it is being sucked in with the air. Eventually, carbon dioxide accumulation in the blood triggers open the spiracles, the vacuum disappears and now gases inside and outside the insect mix by simple diffusion. Direct evidence for this postulated mass inflow of gas is seen in records of tracheal gas tensions, as the following considerations show.

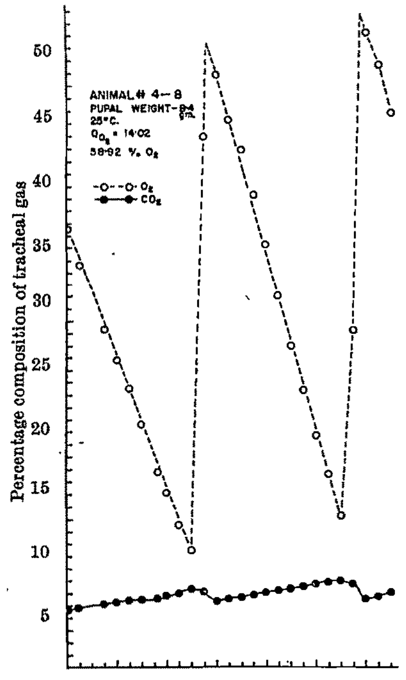

Fig. 4. Record of changes in tracheal gas tensions of a pupa maintained in 59 per cent oxygen

In Fig. 4 it is evident that during the oxygen fall period the oxygen tension within the insect falls at a steady rate which is independent of the gradient of partial pressure driving oxygen into the insect. If simple diffusion were the driving force behind the entry of oxygen, the rate of fall of internal oxygen tension would diminish as the gradient driving oxygen is increased. This is not the case. If, however, oxygen entered by mass flow, then the rate of fall of oxygen tension would remain the same during the entire oxygen fall period, because the number of oxygen molecules entering the tracheal system would be determined almost entirely by the difference in total pressure between the outside and the inside. This is borne out by the observations.

In summary, we see that for most of the time the gas exchange of the pupa is not governed, as we have long thought, by the laws of simple diffusion, in which thermal agitation of molecules is the driving force, but by a different set of laws that govern the mass transfer of gases, where the motive force is difference in absolute pressure. Since discontinuous respiration with its bursts of carbon dioxide is not uncommon among insect orders, and is found in larvæ, pupæ and adults[9], it appears that we may have to re-evaluate several of our usual motions about how some insects breathe.

We wish to thank Mr. Raphael Poritzky for drawing the figures. A detailed description of the methods and complete report of the results of the experiment is in preparation. The investigation has been supported by Grant *H*-1887 from the National Heart Institute of the U.S. Public Health Service.

INSTITUTE OF NUCLEAR SCIENCE OF THE WEIZMANN INSTITUTE OF SCIENCE, REHOVOTH, ISRAEL

By DR. M. A. HIRSHFELD
The Weizmann Institute of Science

THE Institute of Nuclear Science, Rehovoth, is the most recently completed building of the group of scientific institutions which constitutes the Weizmann Memorial, dedicated to the memory of the late Dr. Chaim Weizmann, the first president of Israel. The memorial was established in 1952 and included the already existing Weizmann Institute of Science, the Sieff Research Institute and the Agricultural Research Station. Since its establishment, there has been added the Wolfson Building for Experimental Biology, the Wix Auditorium for lectures and scientific meetings, and the Institute of Nuclear Science. The Institute was dedicated on May 20, 1958, at a formal ceremony in the presence of the President of Israel; addresses were delivered by the Prime Minister, Prof. Niels Bohr and J. Robert Oppenheimer. The dedication was followed by a symposium in the exact sciences: among the participants were physicists from many countries, including Niels Bohr, H. C. Urey, G. Herzberg, J. E. Mayer, J. R. Oppenheimer, J. Weisskopf, S. Chandrasekhar, L. Néel and F. Bloch.

The Institute is set in the midst of the orange groves which surround Rehovoth, overlooking a spacious lawn, flower-beds and lily pond. The building is modern in style, all white, with simple rectangular lines. The main section, covering 4,600 square metres, has two floors above ground and a basement and sub-basement below. The west wing of this section houses the Department of Nuclear Physics; the east wing houses the Electronics, Spectroscopy and Nuclear Magnetic Resonance Sections, as well as the library and seminar rooms. Directly behind the Department of Nuclear Physics is a wing which houses the Department of Isotopes Research with one floor above ground and one below. Connecting the two sections is a corridor containing the common services—machine shop, electronics workshop, electrical distribution centre and administrative offices. The Van de Graaff tower is a separate structure, between the Departments of Nuclear Physics and Isotope Research, connected to both on the basement and sub-basement level. The spectroscopic laboratories are, as usual, located on the sub-basement level to reduce the amount of vibration and temperature fluctuation.

All the services are distributed to the individual rooms through the sub-basement, which extends under the entire building; the wiring and pipes are exposed as much as possible for maximum accessibility. The services include the usual gas, oxygen and compressed air, as well as vacuum and distilled water in the laboratories which require them. The electric lines supplied to outlets in each laboratory include 220 volts from the national grid, 110 volts and a stabilized 220 volts, all at 50 c./s. Free lines from the distribution centre are also connected, which can be used to supply direct current up to 220 volts, either from a generator or storage batteries, or 110 volts, 60 c./s. In Israel's climate, air conditioning is a necessity, and cooling water for this purpose is distributed from a central compressor station. Each corridor—and, in some cases, the individual laboratories—has a separate air circulation system and thermostat to control its own climate.

Because of the nature of the work, it was necessary to adopt special precautions against the harmful effects of radiation—to prevent contamination of rooms and instruments and injury to personnel. The Van de Graaff machine was isolated for this reason. The handling of all radioactive materials will be subject to centralized control. A film badge and blood-testing service will be set up to prevent excessive exposure of the scientists and technicians working in dangerous areas.

The Department of Nuclear Physics, with eight laboratories, the electronics workshop and its offices, occupies about half the main section. Most of the experimental work centres about the Van de Graaff generator, which is housed in a separate, shielded tower and is connected to the main building on the basement and sub-basement levels. The Van de Graaff is a 3-million-volt accelerator; it can deliver up to 100 microamperes and has exceptionally good voltage stability. Among the projects planned are measurements on the energy-levels of light nuclei, the investigation of Delbrück scattering and the measurement of life-times (10^{-9} sec.) of energy-levels excited by Coulomb excitation.

A method for the measurement of very short (10^{-11} sec.) life-times of excited states has been designed and built. It will be used with artificial radioactive sources or in conjunction with the pulsed beam of the Van de Graaff. It employs two beta-ray spectrometers in coincidence and uses microwave techniques to measure the time. It is being used, at present, to measure the life-time of the lowest excited state of platinum-195.

A number of theoretical physicists in the department are working on the shell model of the nucleus, using this model to correlate experimental data and predict energy-levels and transition probabilities for related nuclei. Attempts are being made, too, to develop a unified model, which would incorporate the successful features of both the shell and the collective model.

Another group is working on high-energy physics, measuring the particles ejected from 'stars' produced by 4·5 BeV. pions. The plates for these measurements were exposed to the pion beam of the Berkeley bevatron.

Theoretical work is being carried out as well on high-energy interactions—meson production in nucleon–nucleon and pion–nucleon collisions. The nucleon–pion cascade is calculated by the Monte Carlo method with the help of the Weizmann Institute electronic computer. The work is being done in collaboration with the Department of Isotopes Research.

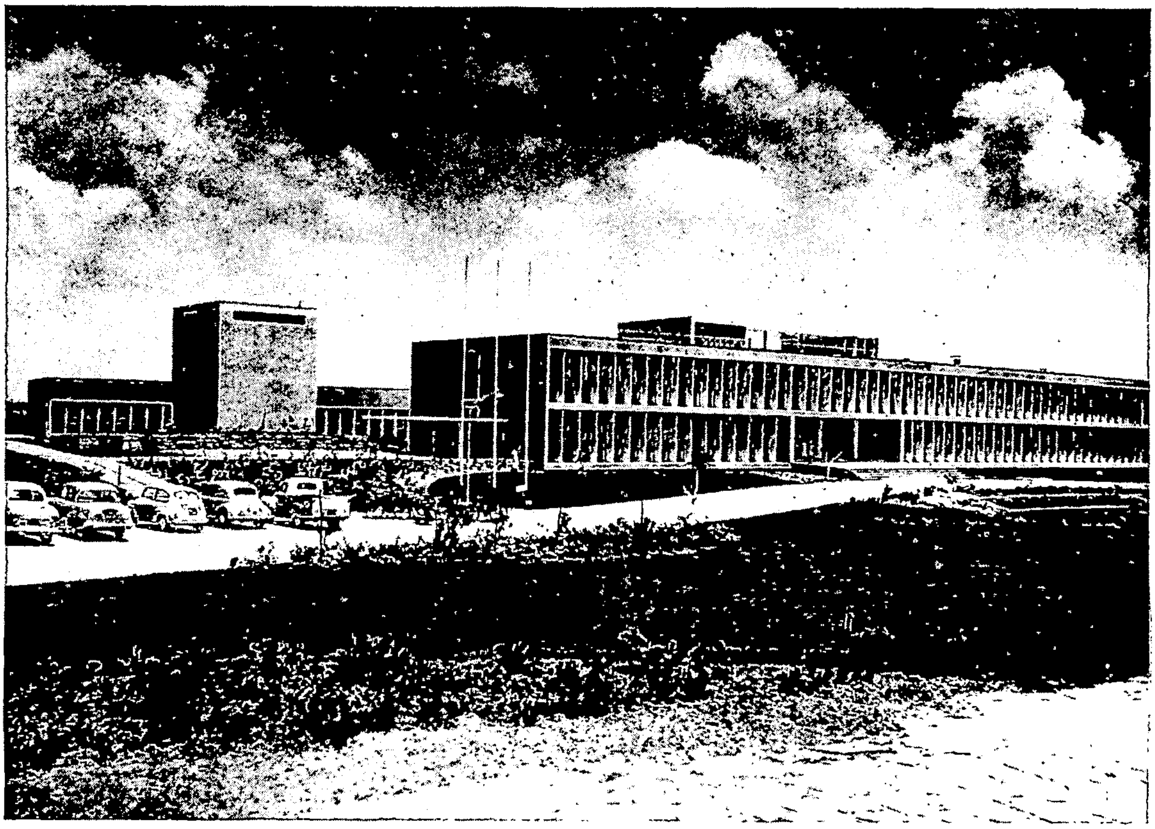

Fig. 1. The Institute of Nuclear Science, Weizmann Institute of Science

The Department of Isotopes Research occupies the rear wing of the building. It has twenty-three laboratories plus facilities for high- and low-level radioactivity work. One of its major activities has been the construction of a plant for the concentration of oxygen-17 and oxygen-18 by the multi-stage fractional distillation of water; it produces concentrations of the former up to 2·0 atomic per cent and of the latter up to 95 atomic per cent. The enriched oxygen isotopes are being used in studying such problems as the point of bond breaking in ester hydrolysis, the exchange of oxygen between organic compounds and water, and the isotope effect in the infra-red spectra of molecules. Four mass spectrometers are available for this work, two of which were constructed at the Institute.

For work with radioactive isotopes special low-level counting rooms have been built using the Faraday cage principle and low-temperature scintillation equipment with coincidence circuits. The projects being worked on include the use of carbon-14 to follow the carbon chain rearrangements during hydration of olefins, and iodine-131 to trace iodine exchange with iodo-aromatic compounds. In co-operation with the Government Water Planning Authority, a study of the flow of underground water is being made, using radiocobalt as a tracer as well as the naturally occurring tritium. A project being carried out together with the Nuclear Physics Department is the isolation of the very short-lived fission products obtained by irradiation of uranium with the thermal neutrons from the Van de Graaff generator. The Department also operates a radioisotope school for training scientists, engineers, physicians and science teachers in the applications of radioisotopes.

The Electronics Department is located in the right wing of the building and consists of nine laboratories. Its facilities comprise a 4 in. laboratory electromagnet and associated instruments built in the Department for the measurement of the magnetic properties of ferro-magnetic substances. There are facilities for the making and shaping of ferrites and standard electronic laboratory equipment.

The research done in these laboratories is in large part connected with the theory of magnetic materials and crossed-field electronic elements. A new process for magnetization reversal has been proposed in the theory of small particle magnets; it had been assumed heretofore that magnetization reversal took place by rotation in unison of the magnetization vectors of the ferro-magnetic ions. It has now been shown that processes called 'curling' and 'buckling' have lower energy and will take place. The results of this theory agree better with the known coercive forces of such magnets.

Work has been done on a crossed-field magnetic amplifier. A clip-on milliammeter based on this amplifier was constructed, and investigations were carried out on a magnetic flip-flop circuit.

Various scientific instruments have been developed in collaboration with other departments of the Institute and outside groups as well. These include several viscometers; one—a microviscometer to measure small amounts of biological substances—is now being used for research in the University of

Birmingham. Another is a high-precision couette viscometer where electrostatic forces are used to supply the restoring torque.

The Spectroscopy Section occupies eight laboratories in the basement and sub-basement of the main building. The work of the section centres around the measurement of the refractive index of gases and liquids in the infra-red. The measurement of dispersion in regions of absorption is a new approach to the problem of measuring intensities in the infra-red. It yields the same information—by an entirely independent method and possibly with improved accuracy.

Located in a laboratory in the sub-basement to provide a stable environment is the large spectrometer-refractometer for the measurement of the dispersion of gases. Designed and built at the Institute, it comprises a high-resolution grating spectrometer and a hollow-prism refractometer of very high sensitivity (1×10^{-7} index units or better); the instrument is evacuated to eliminate atmospheric absorption. Because of the high resolution and sensitivity, the refractive index can be measured through the individual lines of the rotation–vibration bands of a gas. Measurements are being made at present on diatomic gases in the 1·5 micron region and will soon be extended to longer wave-lengths.

To measure dispersion in absorbing liquids, a Perkin–Elmer infra-red spectrometer is being used, together with a specially built critical angle refractometer. Because of the complications introduced by the absorption, the Weizmann Institute electronic computer is used to reduce the results. A method has now been developed for measuring refractive indices of moderately absorbing liquids.

Also available are a large and medium quartz spectrograph for spectrographic analysis and research in the visible and ultra-violet.

The Nuclear Magnetic Resonance Section occupies four laboratories, including chemical preparation rooms. The major piece of equipment is the high-resolution spectrometer which was constructed at the Institute. It utilizes a permanent magnet with a field strength of 7,100 oersteds. The magnet is provided with field homogenizing current shims and a sample spinning turbine. The residual inhomogeneity on a sample of 0·2 cubic centimetre is 10^{-4} oersteds or less. The radio-frequency equipment is tuned to proton frequency only and a specially designed pulsing system eliminates balancing problems. A spin-echo apparatus and unit for solid-state work (a 4-in. electromagnet and Pound spectrometer) are also available.

The nuclear magnetic resonance method is being used to study the rates and mechanisms of very fast proton exchange reactions in solution. The shape of the lines is related to the mean life-time of the molecules between successive proton jumps; the measurements, therefore, enable precise kinetic data to be obtained for very high speed reactions. The reactions being studied are the *p*H-dependent proton exchange in solutions of amines, amides, hydrogen peroxide, water, etc. Work is also being done on the magnitudes and signs of spin–spin constants in liquids, on double quantum transitions, on the Maser effect and on a general theory of exchange narrowing.

NEWS and VIEWS

Applied Electron Physics at the Imperial College of Science and Technology: Prof. Dennis Gabor, F.R.S.

DR. DENNIS GABOR, who has been appointed to a newly created university chair of applied electron physics tenable at the Imperial College of Science and Technology, London, was born in Budapest in 1900. He studied electrical engineering in Budapest and Berlin-Charlottenburg, and after taking the Dr.Ing. degree entered the Siemens-Halske organization, Berlin, as research engineer in 1927. In 1934 he joined the Research Laboratory of the British Thomson-Houston Co., Rugby, and in 1949 he became Mullard reader in electronics in the Department of Electrical Engineering at the Imperial College. He was elected a Fellow of the Royal Society in 1956. Dr. Gabor's research work has covered an unusually wide field and has been characterized by a remarkable inventiveness. Few scientists can have attempted the impossible so frequently or have been so little discouraged by failure to achieve it. After working on high-speed cathode-ray oscillographs, gas-discharge lamps with positive characteristic, light-amplifiers and three-dimensional cinematography, he was attracted in 1944 by the general problem of transmitting information. He created a mathematical framework modelled on quantum theory, now known as 'structural' communication theory, which bridged the gap between the time-description and the Fourier-description of signals, and followed this by a composite of experimental excursions into waveband-saving invention and of theoretical work on the application of communication theory to physics, in particular to physical optics. He later devised a new method of obtaining optical images by 'wavefront reconstruction' which he still hopes might be applied to improving the resolution of electron microscopes. He is at present engaged on the development of a thin, flat, television tube for application to colour television. His many admirers will wish him well in this difficult undertaking.

Geography at Birmingham: Prof. R. H. Kinvig

THE retirement of Prof. R. H. Kinvig marks the end of the first thirty-four years of the Department of Geography at the University of Birmingham. He was appointed there as reader in 1924 to establish the Department, and under his guidance it has become a flourishing honours school from which have graduated several present-day holders of chairs, and a centre for geographical research, especially on the Midlands, with a fine map collection specializing in maps of Birmingham and its region. A Liverpudlian, Kinvig early developed a life-long interest in the Isle of Man, and his "History of the Isle of Man" (1944) shows his wide interest in both historical and human geography. At Birmingham he initiated local studies by his essay on the North-west Midlands for the volume on Great Britain prepared for the International Geographical Union Congress of 1928, and his own continued interest is shown in his editorship of the British Association volume on Birmingham (1950), and his work on the Domesday geography of Warwickshire. He has also travelled widely, and his resulting writings have done much to stimulate studies in Latin America, Poland and southern Africa. His services to the University were recognized by the conferment of a professorship in 1950 and to his subject by his election to the presidency of Section E of the British Association (which he long served as recorder) in 1953, and the presidency of the Institute of British Geographers in 1957.

Prof. David L. Linton

Prof. D. L. Linton, who has held the chair of geography at Sheffield since 1945, has been appointed to succeed Prof. Kinvig at Birmingham. He is now among the most senior of those who graduated from the new honours schools of geography established after the First World War, taking first a general degree in science and then a special degree in geography in 1927 from the Joint School of Geography of King's College, London, and the London School of Economics. He shares with his former teacher and life-long friend and associate in research, Prof. S. W. Wooldridge, an especial interest in geomorphology. He was appointed to the chair at Sheffield at the age of thirty-eight (*Nature*, 106, 106 ; 1945) after service in his old college, King's, and Edinburgh, and a distinguished career in the R.A.F.V.R., where his special talents were used in photographic interpretation. There, as in all his later work, his critical and incisive thinking often resulted in new and fresh interpretations of familiar features. This is seen in his work on delimitation of morphological regions, on drainage patterns and the origin of tors, and in his presidential address to Section E of the British Association in 1957. His long and unobtrusive service as honorary editor of *Geography* is reflected in the current high standing of that journal. Before taking up his duties in Birmingham he is spending a year on research in the Falklands.

Space Science Board

The U.S. National Academy of Sciences has announced the formation of a sixteen-man Space Science Board, "to survey in concert the scientific problems, opportunities and implications of man's advance into space". Dr. Lloyd V. Berkner, president of Associated Universities, Inc., president of the International Council of Scientific Unions and a member of the National Academy of Sciences, is to be the chairman. The Board, besides acting as the focal point for all Academy and National Research Council activities connected with space-science research, will be called upon to co-ordinate its work with appropriate civilian and government agencies, particularly the proposed National Aeronautical and Space Agency, the National Science Foundation, and the Advanced Research Projects Agency, and with foreign groups active in this field.

Darwin, Demography and Development of Life

Three outstanding lectures have now been made available to bigger audiences. The first, by Sir Gavin de Beer, is his well-known lecture on Charles Darwin in the Master-Mind Series of the British Academy (pp. 24. Oxford University Press, 1958. 3*s*. 6*d*.). Besides a succinct introduction to Darwin's life and thought, the lecture provides an admirable exposition of the pre-eminent place of natural selection among contemporary theories of evolution. The second, by the grandson of the genius whom de Beer honoured in his lecture, is the 1958 Rede Lecture, in which Sir Charles Darwin expounds the belief that the present rapid increase in world population holds threats for the future outweighing completely any of the menaces that preoccupy statesmen and politicians (pp. ii+42. Cambridge University Press, 1958. 3*s*. 6*d*.). The third is the inaugural lecture by the recently appointed Quain professor of botany in the University of London, Prof. David Lewis ("The Experimental Approach to Life". Pp. 17. London: H. K. Lewis and Co., Ltd., 1958. 2*s*. 6*d*.). In his lecture, Lewis discusses the experimental approach to life, and shows how physics and chemistry are beginning to play an equally important part with biology. The invasion of biology by physics and chemistry has created a crisis that must be resolved by all who are concerned in biological teaching and research. In research the crisis is partly met by establishing departments of biochemistry and biophysics, but this does not solve the immediate problem of training biologists, which must be carried out in departments of botany and zoology.

Oversea Visual Aids Centre, London

As a result of the unanimous request of an Oversea Visual Aids Conference held in 1956, a Centre has been set up in London from which advice and help will be given on all aspects of audio-visual aids. The Centre, which is to be known as the Oversea Visual Aids Centre (O.V.A.C.), is sponsored by H.M. Government and the Nuffield Foundation. Its director is Mr. G. H. Busbridger, who served in the Educational Service in Northern Rhodesia for many years and afterwards became director of Education in Tanganyika Territory. The Centre has started its activities at Tavistock House, Tavistock Square, London, W.C.1, while alterations are being made to premises at 31 Tavistock Square, which will become its permanent headquarters towards the end of the year. The Centre is controlled by a Board of Governors under the chairmanship of Mr. L. Farrer-Brown, director of the Nuffield Foundation. The Centre will have on permanent display a wide range of projected and non-projected aids, so that visitors can see for themselves examples of the latest equipment used by British manufacturers, as well as cheap non-projected aids made from local materials. It will organize training in the educational use of all kinds of audio-visual aids, in the handling and maintenance of equipment and in techniques of making simple aids from cheap materials. In addition to these services, Governments and individuals overseas will be kept informed of new developments by regular publications.

River Pollution in Britain

In its first report to the Central Advisory Water Committee (pp. 10. London: H.M. Stationery Office, 1958. 9*d*. net), the Trade Effluents Sub-Committee, appointed in October 1956 with Sir Frederick Armer as chairman, to examine existing legislation and the operation of the common law respecting the disposal from trade premises of liquid effluents, concludes that the time has not yet arrived for dispensing with the consent of the Minister of Housing and Local Government before river boards can prosecute for pollution of rivers. It recommends accordingly that the original seven-year period of the Rivers (Prevention of Pollution) Act, 1951, should be extended from 1958 to 1961. In the report, which has been unanimously adopted by the main committee, the sub-committee concludes that, while it is true that river boards generally have shown forbearance, in view of the financial implications of their requirements on industry as well as on local authorities, and through them on the country as a whole, they ought not to disregard the fears of those who are concerned lest they be caught between the difficulties of capital restriction on one hand and possible prosecution on the other. It also seemed desirable to allow a little extra time to industry to pursue research on effluent treatment and to river boards to prepare by-laws laying down permissible standards for effluents. The Committee remarks that it is now embarking on its general review of the law on this subject.

Aslib : Report of the Council

THE report of the Council of the Association of Special Libraries and Information Bureaux for the year ended December 31, 1957, presented at the annual general meeting of Aslib on June 3, records a further increase in membership, from 2,095 to 2,254, including twenty-six technical colleges. Industrial and commercial firms still form the largest single category, totalling 831, compared with 753 at the end of 1956. Besides the acquisition of new and larger premises (3 Belgrave Square, London, S.W.1) which should permit Aslib to develop a research section, establish an exhibition of equipment for library and information work, and expand its library to serve also as a laboratory for testing and demonstrating library equipment and processes, several new short courses were organized during the year, including those on advanced classification, the handling of Russian and other East European literature and the treatment of periodicals. Three special conferences held in London dealt with library services in technical colleges, the preservation of business records and the availability of information on nuclear energy. A grant of £10,000 was received from the National Science Foundation to finance a two-year research project into the efficiency of selected indexing systems, while, with the Royal Society, Aslib is co-ordinating British participation in an International Conference on Scientific Information to be held in Washington in November 1958.

Forest Products Research Laboratory

THE Council for Scientific and Industrial Research has decided that research on the following subjects should be undertaken at the Forest Products Research Laboratory: (1) the pulping properties of home-grown timbers; (2) more work on the general properties of home-grown timbers. An additional scientific officer will be appointed to take charge of the work on pulping. Otherwise all the staff required are to be provided by transfer from other existing work at the Laboratory. The Research Council has also decided that it is not possible to continue indefinitely at the public expense all the work which is at present carried out on timber bending, wood working, composite wood and wood protection. The value of the work is not questioned, but it is considered that the industries concerned which benefit from the work should do it themselves, or pay for it to be done. The Department is therefore informing the industries concerned that its expenditure on work in these fields will diminish progressively and will end in five years time. It will thus be open to industry to carry out the work or to pay the Forest Products Research Laboratory to do it.

Yale Medical Library

THE annual report of the Yale Medical Library for 1956–57, which includes the report of the Historical Library, covers the year ended June 30, 1957 (pp. 33. New Haven, Conn.: Yale University, 1957), and records an increase of more than 160 per cent in the endowed book funds, income from which now approaches 10 per cent of the amount appropriated for purchasing books and periodicals. The film-room maintained by the Library, together with the Audio Visual Centre, seats fifty people, and now contains a 16-mm. sound projector, a slide projector and a microfilm reader, and its use has steadily increased. Accessions of 6,161 during the year brought the Library's holdings to 295,252 volumes (including books, pamphlets and serials) and 26,469 volumes were circulated for outside use, besides 1,055 in inter-library loans. The Library, which has an outstanding collection of Western manuscripts, is one of the foremost in the United States in the richness of its collections for the physician, the scientist and the historian.

Royal College of Science and Technology, Glasgow

THE annual report of the Royal College of Science and Technology, Glasgow, for the year 1956–57, records the initiation of no major developments during that year. During the next ten years the University Grants Committee wishes the College to provide for a student body rising to 2,500. During the quinquennium 1957–62, developments on the teaching side will be mainly to cope with the larger numbers, reduce the size of classes and increase the facilities for advanced study and research. In the reports from Departments, reference is made to the study in the Department of Mathematics of the diffusion of momentum when a jet issues into an outside medium, and the variation of concentration when the jet and the outside medium consist of gases of different kinds; to a varied programme of research in the Department of Natural Philosophy, including an examination of strains of the bacterium *Proteus vulgaris*, and completion of an investigation on the transmission and absorption of highly reflecting films; extension of the research on paddle wheel propulsion in the Department of Naval Architecture, in conjunction with William Denny and Bros., Ltd., by an investigation of the relation between the model results and those from ship trials. In the School of Pharmacy a new series of neuromuscular blocking agents was prepared. A list of recent publications is also included, but further information on research in progress in the various departments is contained in the Report on Research for the Session (pp. 39. Glasgow: Royal College of Science and Technology, 1958). This lists publications departmentally, with a brief abstract of each.

Publications of the Oak Ridge National Laboratory

A LIST of articles in scientific and technical journals and of unclassified reports published during 1957 by members of the staff of the Oak Ridge National

Laboratory has recently been issued (Pp. v+34. Oak Ridge National Laboratory, Union Carbide Corporation, 1958). The articles and reports are listed in separate sections and classified in alphabetical order of authors under the general headings: biology, chemistry, engineering, general, health physics, instrumentation, mathematics, metallurgy and materials, and physics. Many of the papers are available free as reprints from the Central Research Library, Oak Ridge National Laboratory, P.O. Box *X*, Oak Ridge, Tennessee, and others may be purchased through the Office of Technical Services, Department of Commerce, Washington 25, D.C. Some articles were published in 1956, but were not issued until 1957; the 1956 and 1957 articles are distinguished by the prefixes '56' and '57', respectively, before the reference numbers. The authors' names, title of paper and journal reference are given in every case.

Alkali Works in Britain

The ninety-fourth Annual Report on Alkali, etc., Works in England and Wales (pp. 50. London: H.M. Stationery Office, 1958. 3*s*. net) by the Chief Inspector covers the year 1957, when the number of works registered decreased by seventeen to 872 and the number of processes by fourteen to 1,733, due to the concentration of manufacturing operations, particularly at gas-works and by-product plants. The 4,023 units and inspections during the year included 174 special visits by the chief and deputy chief inspectors and nine by Mr. W. A. Damon, who since March has been engaged on special advisory duties. Of the total, 430 visits were to or in connexion with works not registered under the Act, and a further 55 visits were in connexion with colliery spoilbanks. Besides 2,175 quantitative analyses made of gases evolved from the processes in question during the inspections, 965 samples were submitted for detailed examination to the Government Chemist. Complaints were most numerous against cement works and fertilizer granulation plants, and escapes of fumes in excess of statutory limits were recorded on seven occasions, a further ten infractions related to failure to use the "best practical means", the total infractions comparing with 23 in 1956 and 48 in 1955. A general survey of emissions of smoke, grit and dust from registered operations indicated that reasonably satisfactory conditions already exist generally.

Under the same cover is included the annual report for 1957 of the Chief Inspector for Scotland, where the number of registered works decreased by nine to 71 and of processes requiring inspection by thirteen to 101. In the 148 visits of inspection, 56 chemical tests were made. Of the five complaints lodged about fumes from registered works, three related to granulated fertilizer plants and two to paraffin oil works.

Industrial Research in East Africa

The annual report for 1956–57 of the East African Industrial Research Board (pp. ii+8. Nairobi: Government Printer, 1957. Sh. 2) records continued trials on the production of vitreous white-ware bodies, and attempts are now being made to adapt the process to native industry. In the manufacture of bricks and tiles, relatively large additions of sawdust have been possible to some clays, probably those containing a fusible lava, with consequent increased fuel economies, and a pilot-scale continuous kiln has been designed for reconstituting meerschaum from the waste in producing tobacco pipes. Research continued on the mechanical drying of arabica coffee, and fair results have been obtained in estate practice by two methods which should cause no more damage to quality than sun-drying under difficult conditions. Fully wet coffee is severely damaged by a single-stage drying about 100° F., but the damage is less the lower the initial moisture content at which mechanical drying starts. Serious damage to quality is probably associated with damage to viability. In chemical engineering a preliminary investigation has been made on the possibility of condensing natural steam with a jet condenser or an air-cooled surface condenser, and work has commenced on the use of pressure charges for internal combustion engines and on the economies of drying sisal waste. A further attempt to operate a 40-gallon digester for producing methane from sisal waste failed.

East Malling Research Station

An index has been published to provide quick and adequate reference to work carried out at East Malling Research Station and mentioned in the annual research reports since 1913 (Kent Incorporated Society for Promoting Experiments in Horticulture. Abstracts and Index to the Annual Research Reports, 1913–1953, East Malling Research Station, near Maidstone, Kent. Pp. vi+175. East Malling: East Malling Research Station, 1957. 20*s*.). This alone will prove useful to all those concerned with fruit-growing and plantation crops, but the value of the work is greatly enhanced by the fact that the compilers, Dr. F. W. Andrews and Mr. A. C. Painter, have also given a brief abstract of each paper. Thus, a great volume of information has been made available without laborious search. There is an appendix of the pests and diseases mentioned in the reports, under their common English names with their scientific equivalents, including synonyms.

Lundy Field Society

The saddest feature of the eleventh annual report of the Lundy Field Society (Lundy Field Society. Eleventh Annual Report, 1957. Pp. 43+2 plates. Exeter: Prof. L. A. Harvey, The University, 1958. 5*s*.) is the reference by the president, Albion P. Harman, to the real decline in the numbers of puffins on the island. The possibility of the puffin disappearing from the island appears to be very great; within a few years it seems unlikely that the bird will breed there. This is almost certainly due to oil pollution of the sea. Another reference in the report is to the remarkable invasion of tits which took place in October 1957. The immigrants included blue tits, coal tits and great tits, and their times of arrivals coincided with similar records made in other parts of Great Britain. Seven birds new to the island were recorded during 1957; these included the little egret, American stint, tawny owl, nightingale, Richard's pipit and red-knecked grebe. A new feature in the report is an account of the many mesolithic flints unearthed by members of the Devonport High School during a stay on the island. The collection included a number of small worked microlithic blades, a microburin, conical cores, several notched blades, and a fine backed burin or graver, all typical of a mesolithic culture, although possibly of a late date.

A Schoolboy's Survey of Vegetation of a Valley

Blundell's School, Tiverton, may well be proud of R. G. Pembrey, who was awarded the Senior Batterbee Prize in 1957 for an investigation into the factors underlying the differences in vegetation on the north- and south-facing slopes of a steep valley in spring. Pembrey compared the vegetation on the two slopes, analysed the soils at different levels and made observations on the bedding plane of the rocks, recorded environmental factors like soil, temperature and light intensity and made various records comparing the performance of different species on the two slopes. These included the rate of elongation of stems of bramble and yellow archangel, the internode length in ash seedlings, and the times of bursting of beech buds. The differences in the vegetation on the two slopes are due to a more rapid warming of the soil on the south-facing slopes, which allows the growth of a spring ground flora before the bursting of the beech buds. This is directly connected with the far higher light intensity on this slope. On the opposite slope, light intensity and soil temperatures are too low to support a spring flora. A full report of the investigation is described in the *School's Science Magazine,* which contains reports of other interesting work by schoolboys.

Volcanic Eruptions in Kamchatka

The extinct or dormant volcano Bezymyannyi (also known as Sopka Bezymyannaya), belonging to the Klynchevsky group of volcanoes of Kamchatka, revived its activity on September 29, 1955, in the form of a series of volcanic earthquakes, followed on October 22, 1955, by eruptions terminating, on March 30, 1956, in a gigantic explosion which removed the greater part of the cone and formed a new crater-caldera. The progress of this activity was observed by G. S. Gorshkov and his companions and is described by him in two articles (*Bull. Volcan. Station,* No. 26, *Acad. Sci. U.S.S.R.,* 1957 ; *Priroda,* 1, 61 ; 1958). The violent explosions of this volcano gave rise to large masses of volcanic ash which, mixing with melting snow, formed a series of mud flows, some 60 km. in length with a calculated volume of 3 cubic kilometres. These flows became covered with a large number of secondary fumaroles in such a way that the whole district resembled the Valley of Ten Thousand Smokes of the Katmai eruption of 1912 in Alaska. According to Gorshkov, the calculated total energy of the volcanic explosive activity was 4×10^{23} ergs, while the total thermal energy evolved was $3{\cdot}6 \times 10^{25}$ ergs. This shows that the force of the eruption was due to the thermal energy of the magma and that the gas acted mainly as the transformer of the thermal energy into the explosion energy. During the final stages of the eruption a large plug-dome of andesitic lava was intruded in the crater-caldera of the volcano.

Reduction of Evaporation from Reservoirs

In an article in the *World Meteorological Bulletin* of April 1958 and in a report on the use of cetyl alcohol in solution to reduce evaporation from reservoirs Mr. F. Grundy gives an account of an experiment conducted on Malya reservoir in Tanganyika Territory during August 1957 (Memoirs of the East African Meteorological Department, 2, No. 11 ; 1958. Nairobi : East African Meteorological Department, 1958. Sh. 4). The subject is one of particularly great importance in tropical areas where loss of water by evaporation can be several times the volume drawn for use. The work in East Africa began with tests in evaporation pans in the grounds of the Meteorological Office at Nairobi, which showed reduction of loss by about 60 per cent. Work on the Malya reservoir (130 acres) was more difficult because of disturbance by wind, and it was found better to use the alcohol dissolved in such solvents as kerosene rather than in solid form. The solution has to be applied continuously from sources on the upwind shore or preferably, because of better adjustment to wind changes, from a boat. The observations were made during the dry season to avoid complications due to rain. By computing the evaporation-loss from the inflow and outflow and comparing with evaporation from neighbouring evaporation pans it was estimated that the evaporation-loss was reduced by 11 per cent. The amount of cetyl alcohol used was 18 lb./day. It is not poisonous to man or animals, but its effects on fish are not yet known. Mr. Grundy considers that the experiments show an adequate film of cetyl alcohol can be maintained, but that further research is needed, especially on the method of applying the substance and avoiding wastage from its oxidation by organic matter. The cost is not likely to be excessive.

Nomenclature of Cultivated Plants and of Fungi Pathogenic to Man

It is now generally accepted that agreed international codes of nomenclature are essential to progress and unity of effort in the biological sciences ; and cultivated plants, being essential to civilization, should be brought fully within "a precise, stable and internationally accepted system". So states Article 1 of "The International Code of Nomenclature for Cultivated Plants" (1958), now published by the International Bureau for Plant Taxonomy and Nomenclature of the International Association for Plant Taxonomy (106 Lange Nieuwstraat, Utrecht, and Royal Horticultural Society, London. 2*s.* 6*d.*). In this short but valuable publication, to which many distinguished botanists have contributed, all relevant issues are considered with clarity and precision. In the same general category, but dealing with very different subject-matter, the Medical Research Council has now published a revised edition of Memorandum No. 23, first issued in 1949 ("Nomenclature of Fungi Pathogenic to Man and Animals—Names recommended for use in Great Britain". Second edition. Pp. iii+14. London: H.M. Stationery Office, 1958. 1*s.* 3*d.* net). Here, again, it is noted how much progress in medical mycology has been hindered by the multiplicity of names for fungi associated with certain human and animal diseases. The nomenclatural issues here can be very complex indeed, and both knowledge and judgment are essential to sound decisions. In this small pamphlet an exacting task has been ably performed.

Peruvian Orchids

The Orchidaceae not only vie with the Compositae as a family comprising a vast number of species—somewhere between 15,000 and 35,000 according to contemporary estimates—but they are also undoubtedly among the most advanced group of the monocotyledons. A further contribution to our knowledge of this family comes from Peru, where some 120 genera and 900 species have been recorded. A recent publication deals with 26 genera and 629 species (Chicago Museum of Natural History. *Fieldiana*: *Botany*. Vol. 30, No. 1: Orchids of Peru. By Charles Schweinfurth. Pp. viii+260. (Publication 837.) Chicago: Chicago Natural History Museum, 1958. 4.50 dollars). In the Peruvian and Colombian Andes, indeed, the orchid flora apparently reaches its richest expression. As the author points out, although there have been many collecting expeditions to the Peruvian Andes, and much material stored away in herbaria, no comprehensive flora of the region has been undertaken for 130 years. The monograph is well illustrated by line drawings.

Biology in the Far East

A Congress has been arranged by the University of Malaya, to be held in Singapore during December 2–9, to celebrate the centenary of the publication of the theory of evolution by Charles Darwin and Alfred Russel Wallace, and the bi-centenary of the publication of the tenth edition of "Systema Naturæ" by Linnæus, and to provide a forum for scientists in South-East Asia who were not able to attend the fifteenth International Congress of Zoology in London in July. Recognition has been given to this Congress by various learned societies which have nominated representatives to attend and contribute papers to the symposia. Financial support has been gained from numerous sources, whereby it has been possible to issue invitations to a number of biologists in various parts of the world to attend the Congress as guests of the University of Malaya. Valuable help is also being given to the organization of relevant exhibitions. The organizers of the Congress hope to enable some distinguished visitors to visit the Federation of Malaya to deliver additional lectures at appropriate places, and it is also expected that the various exhibitions will be sent into the Federation of Malaya for display, so that the maximum benefit can be gained from the occasion.

The Congress will open on December 2 with an address of welcome to the visitors, and a presidential address, followed by lectures introducing the Indo-Malayan region, and the concept of organic evolution. The following six days will be devoted to a series of symposia in the fields of botany, ecology, general systematics, evolution, genetics and anthropology. Visits to local places of interest will be arranged during December 2–9, and a number of excursions will be held immediately afterwards.

Prospective participants should communicate the title of any scientific paper offered, with its length, to Prof. R. D. Purchon, University of Malaya, Singapore, from whom further information can be obtained.

U.S. National Science Foundation: Senior Postdoctoral Fellowships

The National Science Foundation, Washington, D.C., has announced the award of 54 science faculty fellowships for the academic year 1958–59, offered as a means of improving the teaching of science, mathematics and engineering in American colleges and universities. The Foundation has also announced the award of 27 senior postdoctoral fellowships in the sciences for the academic year 1958–59, selected from 155 applicants. Science faculty fellows were selected from 440 graduates from all parts of the United States and its territories on the basis of demonstrated ability and special aptitude for science teaching and advanced training. Senior postdoctoral fellowships were awarded to scientists with ability and special aptitude for productive scholarship. Ten awards were made in the life sciences, and fifteen in the physical sciences, including a number in inter-disciplinary fields. Two awards were made in convergent fields. Science faculty and senior postdoctoral fellowships carry stipends approximately equal to the regular salaries of the recipients. These stipends may be applied towards study or research in an accredited non-profit institution of higher learning in the United States or abroad.

Announcements

The ninth International Congress on Astronautics will be held in Amsterdam during August 25–30. Further information can be obtained from the British Interplanetary Society, 12 Bessborough Gardens, London, S.W.1.

The Golden Jubilee Autumn Meeting of the Institute of Metals will be held in Birmingham during September 22–26. Further information can be obtained from the Secretary, Institute of Metals, 17 Belgrave Square, London, S.W.1.

The next joint meeting of the Challenger Society and representatives from the Marine Laboratories (Development Commissioners' Scheme) will be held at the Dove Marine Laboratory, Cullercoats, and King's College, Newcastle upon Tyne, during September 18 and 19. Further information can be obtained from Dr. H. O. Bull, Dove Marine Laboratory, Cullercoats, North Shields, Northumberland.

The fourth Reinforced Plastics Technical Conference, organized by the British Plastics Federation, will be held at the Hotel Metropole, Brighton, during October 21–24. There will be sessions on the properties of basic materials, applications, manufacture and user interests. Papers will be preprinted and circulated before the conference. Further details can be obtained from the British Plastics Federation, 47–48 Piccadilly, London, W.1.

The British Weed Control Conference, 1958, organized jointly by the Society of Chemical Industry and the British Weed Control Council, will be held at the Hotel Metropole, Brighton, during November 3–6. Further information can be obtained from the Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

The National Institute of Agricultural Botany is holding a conference on "Herbage Seed Production" in Cambridge during November 18 and 19. Further information can be obtained from the Secretary of the Institute, at Huntingdon Road, Cambridge.

The Artemis Press invites submission of manuscripts for a prize of £150, which will be awarded for an academic work in mathematics, astronomy or physics. Both monographs and more general works will be considered; they need not be original in content, but relevance to fundamental topics and elegance of treatment are desirable. All manuscripts submitted will be considered for publication. Further information and entry forms can be obtained from the Artemis Press, Ltd., 25 Walpole Street, London, S.W.3.

GEOLOGICAL MAP OF THE WORLD

THE Commission for the Geological Map of the World met in Paris during March 31–April 12. This Commission was founded in 1910 at the Stockholm International Congress and has been reorganized twice since the Second World War. At the Mexico International Geological Congress in 1956 two Sub-Commissions were created: (1) for the Tectonic Map of the World, and (2) for the Metallogenic Map of the World. The Paris meeting was organized to establish an international basis and co-ordination for an immediate start on these three maps of the World: geological, tectonic and metallogenic, on an agreed universal scale, legend and principles of construction. The Commission's aim is to promote the construction of such maps for the following regions of the Earth: North America, South America, Europe, Africa, U.S.S.R., Asia, Oceania, Arctic and Antarctic. The Commission is planning to publish a Geological Atlas of the World at the scale 1 :10,000,000 based on maps at the scale of 1 : 5,000,000. The latter scale is suggested for the tectonic and metallogenic maps. Detailed programmes for the realization of these maps were worked out by the Commission and a number of specific recommendations from various countries or groups of countries were accepted. The aim of the metallogenic map is to record the relations between geology, tectonics and the mineral deposits in any given region. It was also suggested that prior to the construction of such maps, mineral maps accompanied by indexes of mineral deposits should be prepared. It is hoped that these maps, at least in manuscript draft form will be ready for display at the International Geological Congress to be held in Copenhagen in 1960.

Sixty-one countries were represented at the Paris meeting by delegates and assisting geologists. The president of the Commission, elected in 1952, is F. Blondel, who is assisted by his secretariat at 20, rue Monsieur, Paris 7^{e}, France. The vice-presidents for the selected regions are as follows: North and Central America, W. D. Johnston, jun.; South America, A. R. Lamego; Europe, A. Bentz; Africa, F. Dixey; U.S.S.R., N. A. Beliaevsky; Asia, V. P. Sondhi; Oceania, J. M. Rayner.

A Select Committee under the presidency of F. Dixey examined suggestions for the general legend of the Geological Map of the World and drafted a set of recommendations. Similar work was done for the tectonic map by the special sub-commission (president, N. S. Shatsky; secretary, A. A. Bogdanov), and for the metallogenic map by the special sub-commission (president, W. D. Johnston, jun.; secretary, P. Routhier). Possibilities of preparing a coal map of Europe were also discussed.

Besides the meetings of the Commissions, a number of meetings dealing with various associated problems were held, such as the International Geological Abstracting Service, presided over by H. M. E. Schurmann, the Committee on Stratigraphy, the Mediterranean-Alpine Committee and others.

During the fortnight's working of the Commission, a number of official receptions were held, which allowed a closer contact between the visiting geologists and their French colleagues, and the strenuous work of the Commission was relieved at the week-end by a visit to the cathedral towns and the castles of the Loire region. The meeting of such a number of geologists from so many countries, animated by the same enthusiasm and purpose, testifies to a most healthy situation in the world of international science. The effective and profitable results of the meeting are, in no small measure, due to the most efficient organization of the Commission by its president and secretariat.

MUSEUMS ASSOCIATION CONFERENCE

THE sixty-fourth annual conference of the Museums Association was held in London during July 7–12, and was attended by more than 700 delegates, among whom were some 70 members of De Museumdag from Holland. It was held in Britain to enable the British delegates to return in some measure the hospitality and courtesy extended to them on their visit to Amsterdam in 1956.

The meetings were held in the Beveridge Hall of the University of London and the official welcome was given by the Minister of Education (the Right Hon. Geoffrey Lloyd), who stressed the view of his Ministry that there should be more co-operation between local authorities and private bodies in the maintenance of museums. He welcomed the increasing part that museums were taking in the educational field and said that the Government was well aware of the difficulties of the small museum. Various suggestions had been made and meanwhile his Ministry was watching with interest the development of plans for a regional museum service.

During his presidential address Sir Philip Hendy, director of the National Gallery, dealt with various problems in the museum and art gallery field. First, he mentioned that the tremendous assistance given by the Carnegie United Kingdom Trust in the past is likely to be reduced in the future. He expressed the strong opinion of the Association that it should be replaced by Government assistance of a substantial nature. He then dealt with the recent controversy arising from the enlightened provisions of the Finance Act, 1956, whereby works of art could be accepted in payment of death duties. It was discouraging that a difference had arisen between local and national claims over the Chatsworth treasures. He believed that objects of the highest quality should go to the national collections, as they and they alone could provide the proper context and setting for such material. He also felt that the provisions of the Finance Act could be used for other objects that would be useful in building up the collections of local museums and would otherwise be almost certainly exported from Great Britain.

Dr. A. B. de Vries, president of De Museumdag, also spoke and enumerated some of the qualities necessary in a museum curator.

A complete session was given to a discussion concerning museums in the Commonwealth and Overseas with especial reference to the training of curators. Dr. D. B. Harden, chairman, in opening the discussion, referred to the progress that had already been made with training schemes in South Africa and Canada and expressed the hope that an overseas secretary would be appointed at no distant date to deal with the furtherance of international relationships between the home country, the Dominions and other smaller countries within the Commonwealth. Subsequent speakers included professional museum staff from parts of Africa, Pakistan and Singapore. It was stated by Prof. P. L. Shinnie of the University of Ghana that countries which had recently achieved their independence would not be content with having their museums staffed by English people. On the other hand, Africans with good degrees would scarcely be willing to accept museum posts when there were far more attractive openings in the Civil Service. He felt that the training of technicians could be dealt with in Africa but that curators should have the benefit of a European tour of representative institutions. Dr. L. S. Russell, secretary of the Museums Association in Canada, stated that an inquiry had, contrary to the accepted idea, shown that the chief difficulty in that country was not geographical separation but diversity of subject-matter.

Another session, under the chairmanship of Dr. W. E. Swinton, was devoted to museum architecture. It was opened by Mr. Sheppard Fidler, city architect of Birmingham, who described in detail the reconstruction of the galleries which had been so severely bombed during the War. Dr. H. L. C. Jaffé, Amsterdam, dealt with the many building schemes which had taken place in Holland and several other speakers contributed to the discussion.

In proposing a resolution which deplored the continual negative attitude of H.M. Government towards granting assistance to local museums and art galleries, and urging that everything should be done to acquaint those in authority and others with the facts, Sir Mortimer Wheeler felt that the Standing Commission was an eminent body but of no service to provincial museums. He stressed the urgent need for analytical information and considered that a Royal Commission on the whole subject was long overdue. Government help on a modest scale was needed, and he felt an analogy with the successful University Grants Committee was sound and could be fruitful.

At the annual general meeting, Dr. W. E. Swinton, British Museum (Natural History), was elected president and Sir Philip Hendy and Prof. Lionel Robbins vice-presidents for the ensuing year.

A successful feature of the conference was the large number of working parties which had been arranged at the larger museums and art galleries in London. These were much appreciated by both the Dutch and British delegates and led to many useful discussions in which small groups benefited greatly from the expert knowledge of the staffs concerned.

Receptions were on a lavish scale and included an evening one at the National Gallery which was graced by the presence of Her Majesty Queen Elizabeth the Queen Mother, patron of the Museums Association, a spectacular reception at the Guildhall given by the Corporation of London and smaller groups at the Wellcome Historical Museum of Medical Science and the Iveagh Bequest, Kenwood. The annual dinner was held at the Goldsmiths' Hall and the conference concluded with field meetings at Brighton, Petworth House, Saltwood Castle and Canterbury, Cambridge and St. Albans. It was decided to hold the next conference in Worthing during June 15–20, 1959.

THE BACKGROUND TO SPECIALIST TECHNOLOGICAL EDUCATION

By Dr. M. L. R. PETTERSSON
Brunel College of Technology, Acton, London, W.3

HOW does, how *should*, the content of a course for the diploma in technology differ from that of a traditional honours degree course ? It is the present purpose to attempt, in part, to give an answer to this question. The tradition of technical education, often by apprenticeship, can be traced back to the earliest stages of human society. The educational tradition of scholarly book learning, on the other hand, has evolved only in the past 1 per cent of human existence. The medieval universities and schools took their character almost entirely from the scholarly tradition. Yet it is by a blending of these two kinds of activity that the flowering of modern science has arisen; to produce the change from the agricultural to the industrial stage of human society.

To what extent is present-day education adapted to the needs of our children, in contemporary industrial society ? We have in Britain, comparatively, an extremely good educational system. But since society is developing with such rapidity, both recent reforms and further changes appear inevitable. Confining attention to grammar school and college education, the following five points are offered for consideration.

(1) At the Renaissance, attention to ancient writers was a progressive change. But to-day, whether in English, languages, history or the sciences, too little consideration is often given to the past ten, thirty and a hundred years.

(2) Though the medieval scholarly tradition of book learning has already been much blended with practical manual activities, most school and some college laboratories could do with ten times the costly equipment, space and technician assistance, to give fully effective courses.

(3) The medieval scholarly tradition is mainly of 'pure' studies. It is suggested that in the later years of nearly everyone's education there could well be a higher proportion of applied aspects, both those of use to the general citizen and those which are specifically vocational. This could make higher education

both more interesting as well as a better preparation for later life.

(4) While the Renaissance, plus printing, greatly increased the store of written work available for study, the recent upsurge of science has increased our available scientific written knowledge and material equipments vastly more. Dr. D. J. Price, in *Discovery* of June 1956, gives evidence which suggests that our total scientific knowledge is roughly doubling every 10–15 years, and has been doing this for at least two centuries. The rate of increase is about a hundred-fold per century; and thus, since the schooldays of Newton, scientific knowledge seems to have increased by something like a million-fold. This has resulted in (*a*) the extended duration of science courses, and in (*b*) a further specialization in ever narrower sectors of our total knowledge. The special degree course has been built on top of the General, and university entrance is now preceded by a stiff two or three years in the sixth form in schools. But since lecturers and examiners find it very difficult to drop out older points of detail when new data are incorporated into a subject, there is still often an unhealthy overload of factual material to be memorized, as the Science Masters' Association has recently pointed out. One suspects that the amount of work necessary for graduation, a century ago, may have been little or no more than the work necessary for three General Certificate of Education (Advanced Level) science passes to-day—and perhaps the high-school student deserves more public credit for his achievement.

(5) The enormous increase of modern scientific knowledge has necessitated progressive specialization of courses. But one result is that, for each student, a greater proportion of the sectors of modern knowledge remains neglected. On the other hand, in an industrial democracy, it is most desirable that a large proportion of citizens should be properly equipped with a balanced outlook based on all branches of scientific and other knowledge; with "a broad outlook and a sense of spiritual and human values" (Circular 323). Thus a case can be made for devoting some 10 per cent of each week of sixth-form and college time to achieving this end.

The above five points arise partly from the rapidity of scientific advance and partly from the character of earlier scholastic education. They may be summed up as suggesting a further shift of emphasis: (1) from old to new; (2) from book learning to practical; (3) from pure to applied, including vocational; (4) from an encyclopædic to a more selective approach, and to still greater specialization of the main subject; but (5) towards developing, on the side, a balanced and integrated cultural background covering the whole range of modern knowledge.

Viewed in this kind of historical perspective, the real or potential virtues of the new courses for the Diploma in Technology are clearly apparent. The National Council for Technological Awards, which sponsors these courses, has given the teaching colleges considerable freedom in the design of syllabuses, and these are under constant review. Thus, while maintaining a serious academic coverage of principles, many older topics can be dropped out in favour of newer ones of contemporary relevance. The laboratory time of the eight terms at college is reinforced by four six-month periods of actual industrial employment; and the whole emphasis of the later years of the course is deliberately vocational and applied. In many places the importance of a selective rather than an encyclopædic approach is forcefully realized; while each course is at least as specialized as that for a special degree. In addition, there is an earnest groping towards a suitable development of non-vocational liberal studies, to occupy some 10 per cent of the time-table. The entrance requirement for a diploma in technology course is approximately the same as for a university, though National Certificates are recognized besides the General Certificate of Education. Some students are entered by industrial firms, while others come direct from school sixth forms. Most, though not all, diploma courses are conducted on the sandwich principle. Thus, in each of the four (or five) years, two terms at college are succeeded by six months in appropriate industrial employment; and it is expected that after the four years of scientifically and technologically up-to-date education and experience the average diploma holder will be at least as effective a member of his firm as the average graduate becomes after a further year or two of postgraduate training. Incidentally, the diploma qualification is now recognized as at least the equivalent of a degree by the Burnham Committee. Thus, it is also a route for the recruitment of younger school teachers, who will arrive at school with a much fuller understanding of contemporary life.

The annual intake of students to the diploma courses is at present 736, and is rising rapidly. 1957–58 is only the second year of normal enrolment, and in a few years the intake is likely to be several thousand. The courses are mainly conducted in the new colleges of advanced technology, and where there is a research tradition. The students attending come from all parts of the country. By last autumn the number of subjects for which courses had received the provisional approval of the National Council, at the different centres, was as follows:

Battersea, London	7 subjects
Birmingham	7
Northampton, London	7
Brunel, London	6
Chelsea, London	3
Northern, London	3
Woolwich, London	3
Borough, London	2
Loughborough	2
Cardiff	1
Kingston, Surrey	1
Wolverhampton	1

In a few cases these courses have not yet commenced, but on the other hand in some colleges, especially Battersea College, the courses are run in duplicate—sandwich plus full-time.

In conclusion, it may be mentioned that the courses running last spring, numbering forty in all, had the following subject distribution:

Mechanical and production engineering	9 courses
Electrical engineering	8
Applied chemistry, etc.	7
Physics	5
Metallurgy	3
Aeronautical engineering	2
Chemical engineering	2
Mathematics	2
Applied biology	1
Civil engineering	1

The engineering and other studies which have developed from the basic work done by the old flint knappers, bronze smiths and millwrights are well represented; but there is already one course, at Brunel College, dealing with the industrial aspects of living organisms.

OPENCAST MINING IN BRITAIN

THE Opencast Coal Bill, which received a second reading in the House of Lords on June 26, repeals the Defence Regulations under which opencast coal operations are now carried on. In moving the second reading, the Minister of Power, Lord Mills, said that the Bill was the last and largest step in replacing by statutory provisions the Defence Regulations relating to land. The Water Bill and the Land Powers (Defence) Bill had been other measures to that end. Lord Mills said that opencast coal working on a substantial scale began in 1942 to help relieve the acute shortage of coal that had then developed, and since then the opencast sites had produced 160 million tons of coal from slightly less than 110,000 acres, mostly agricultural land, or about 0·25 per cent of our total agricultural land. The opencast output was now about 14 million tons a year, about a quarter of which was large coal, and would fall in two or three years to about 4 million tons unless new sites came into production. To avoid a resumption of imports and replacing restrictions on supplies of house coal we must maintain a substantial level of opencast output for some time and would probably need some opencast coal for the next ten years. Lord Mills assured the House that he would give very close attention to the National Coal Board's plans for opencast coal output with the view of maintaining adequate supplies of coal while doing the minimum damage to agriculture and amenity. In recent months we had been able to defer indefinitely the working of several sites and he hoped the improved position would enable us to be a little more selective.

Lord Mills said that when the new Bill came into operation the National Coal Board intended, whenever possible, to obtain the land or rights in land which they needed for opencast working by agreement, and he gave as one reason for the new legislation the high standard of agricultural restoration after opencast coal working which we had developed. To ensure the maintenance of that high standard we must make special arrangements for close Ministerial control of opencast coal production. He stated categorically that it was the Government's intention at least to maintain present standards of restoration, and, in particular, to require the Board, in the national interest, to restore all agricultural land to the general standard laid down in a code of restoration which was adopted in 1951 and is now being improved as a result of recent discussions between his Department and the National Coal Board and the agricultural organizations. This code provides for five years special treatment of restored agricultural land, and under the Bill the Agricultural Departments would continue to carry out this treatment for the Board, while the Forestry Commission would act similarly for woodland.

In explaining the compulsory powers under the Bill, Lord Mills said that, by Clauses 4 and 6, the Board was empowered to acquire the rights needed to hold, for up to ten years, land at present held under requisition from opencast coal disposal points and stocking grounds. Clause 9 provided that no compulsory rights order could be made against an occupied dwelling house, its garden and certain other land held with it, while every compulsory rights order would be subject to confirmation by the Minister of Power under a procedure which ensured a right to object and to have objection heard. In replying on the debate, Lord Mills said that he was convinced that it would have been wrong to suggest any shorter period than ten years for the operation of the Bill. He was not entirely satisfied that the Bill adequately covered the possible effect of opencast coal working on water supplies, but the Government did not intend that the powers it conferred should enable the National Coal Board to over-ride the Water Act, 1945, or bye-laws made under that Act.

SYNOPTIC CLIMATOLOGY

SYNOPTIC climatology provides mean values and other statistical parameters of the temperature, cloudiness, precipitation and so on, which are related to the type of air mass and the large-scale distribution of air pressure. It differs in this way from the older type of climatology based more or less exclusively on time of year, which lumped all the atmospheric circulation types together. Types of circulation outside the tropics are by no means closely related to season, however, though some are more frequent in one season than in another. Moreover, the weather in a given type can differ greatly from one season to another, as is evident from the difference between winter and summer in the effect on temperature over western Europe of a persistent high-pressure area over Scandinavia. Such an area has easterly winds to the south of it.

Knowledge of the weather associated with a given type is essential to the weather forecaster, who works by first predicting the pressure distribution and then the associated weather. These two stages are more clearly marked in the modern numerical method of forecasting based on the approximate solution of the equations of motion of the atmosphere by replacing the differential coefficients by finite differences than in the older and more subjective method.

A notable contribution to the synoptic climatology of the British Isles was Dr. Belasco's "Characteristics of Air Masses over the British Isles" (Meteorological Office Geophysical Memoir, No. 87 ; 1952).

Now the Weather Service of the Federal German Republic has published an even more elaborate synoptic climatological study in Dr. K. Bürger's work, "Zur Klimatologie der Grosswetterlagen, ein witterungsklimatologischer Beitrag"*. This is a truly monumental record of the synoptic climatology of western Germany (including Berlin). *Witterung*, a useful word for which there is no single equivalent in English, implies "the constant element in a sequence of weather situations over several days", and *Gross-*

---

* Berichte des Deutschen Wetterdienstes. Nr. 45 (Band 6): Zur Klimatologie der Grosswetterlagen, ein witterungsklimatologischer Beitrag. Von Kurt Bürger. 79 s. mit 2 Abbildungen und 36 Tabellen im Text, sowie 13 Zahlentafeln und 8 Bildtafeln im Anhang. (Offenbach/M.: Deutschen Wetterdienstes, 1958.) 46.60 D.M.

wetterlage means "the main constant circulation and main pressure distribution over the area studied during the period for which the weather type (*Witterung*) persists".

Bürger's work is based on the analysis by punched cards of the observations of temperature, cloud and precipitation at Berlin, Bremen, Karlsruhe and Munich over the period 1890–1954 (omitting 1945). Twenty-eight types of circulation (*Grosswetterlage*) are distinguished, taken for the period to 1952 from Hess and Brezowsky's "Katalog der Grosswetterlagen Europas" (Berichte des Deutschen Wetterdienstes U.S.-Zone, Nr. 33 ; 1952).

The statistics of the types and of the elements considered in relation to the types set out in numerous tables and diagrams with seventy-eight large pages of commentary include the monthly means for each type, with deviations from the means, and much additional information—such as the types which bring the earliest and last frosts and snowfalls of the year.

As an example of the seasonal differences in the weather associated with circulation types it is shown in one of the tables that while southerly and south-easterly winds associated with an anticyclone are nearly the coldest at Berlin in winter, with a mean temperature 5° C. below the seasonal mean, by May they have become warmest, with a mean temperature 3·1° C. above the seasonal mean. There are naturally differences in the effect of different circulation types at the four stations, notably between Bremen and Munich.

The effect of continentality is clearly shown in the dependence of the standard deviations on place and type. The frequency of temperatures and precipitation between specified limits and occasions of extreme values are listed and referred to their circulation type.

There is no discussion of upper air conditions, but perhaps they will be similarly dealt with later.

EFFECT OF COLCHICINE ON THE UTILIZATION OF LABELLED THYMIDINE DURING CHROMOSOMAL REPRODUCTION

By L. F. La COUR
John Innes Horticultural Institution, Bayfordbury, Hertford, Herts

AND

Dr. S. R. PELC
Medical Research Council Biophysics Research Unit, King's College, Strand, London

It has been accepted that labelled thymidine is incorporated only into deoxyribonucleic acid[1]. Taylor *et al.*[2] used thymidine labelled with tritium to provide information on the mode of chromosome replication, and colchicine was employed to assist in clarifying the way in which the tracer was inherited by the daughter chromosomes in the meristematic cells of roots of *Vicia faba*. Autoradiographs over chromosomes were obtained by the stripping film technique in squash preparations. Taylor and his collaborators grew seedlings in nutrient solution containing thymidine-^{3}H for 8 hr., then transferred the plants to nutrient solution containing a concentration of 0·05 per cent colchicine, and fixed root tips 18 and 42 hr. after the start of labelling. Colchicine, by inhibiting spindle formation, allowed them to distinguish with certainty the first (X_1) and second (X_2) mitosis after labelling. *C*-metaphases with the normal complement of 12 chromosomes would be expected in the roots fixed at 18 hr. and a high proportion of *C*-metaphases with 24 chromosomes in those fixed after 42 hr.

In *C*-metaphases of X_1 cells they report that both chromatids in each of the 12 chromosomes were equally labelled along their length, while in *C*-metaphases of X_2 cells usually only one of the chromatids in each of the 24 chromosomes was labelled along its length. A few X_3 cells (48 chromosomes) were found in roots fixed after 42 hr., in which about half the chromosomes were unlabelled, the remainder being labelled in one chromatid. In X_2 and X_3 cells a few chromatids were labelled along only part of their length, but in these instances the sister chromatids were labelled in complementary segments. This exchange was attributed to somatic crossing-over.

These findings were interpreted as showing that the deoxyribonucleic acid is synthesized as an intact unit, and that reproduction in chromosomes which behave as if they consist essentially of one molecule is by means of a template based on a double-helix model, as envisaged by Watson and Crick[3]. In this system each chromatid after replication would consist of two strands, one with 'old' and one with 'new'

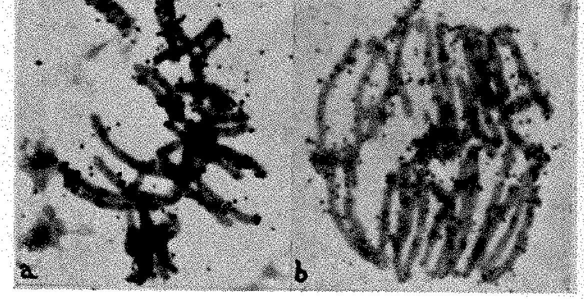

Fig. 1. Autoradiograph of X_2 metaphase (*a*) and X_2 anaphase (*b*) from roots of *Vicia faba* grown for 12 hr. in tap-water containing thymidine-^{3}H followed by 36 hr. in pure tap-water. Squash preparations stained in toluidine blue after autoradiography. Note in metaphase labelling in both chromatids of *s*-chromosomes at top left and right, unequal labelling in others and at bottom left labelling in discrete homologous regions of both chromatids (× 1,300)

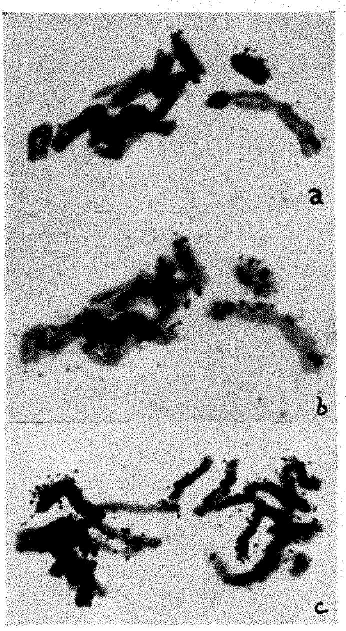

Fig. 2. X_1 *C*-metaphase and X_1 *C*-anaphase (*c*) from roots of *V. faba* grown for 1 hr. in 0·05 per cent colchicine prior to treatment for 8 hr. with colchicine and thymidine-^{3}H, followed by 0·05 per cent colchicine in tap-water for 12 hr. Squash preparations stained in Feulgen before autoradiography. (*a*) Focused on the chromosomes; (*b*) focused on photographic grains; (*c*) *C*-anaphase. In the metaphase an *M*- and an *S*-chromosome show labelling in one chromatid only; one chromatid of an *S*-chromosome is unlabelled in the *C*-anaphase. (× 1,300)

deoxyribonucleic acid, which are in turn separated during synthesis for the X_2 mitosis.

This interpretation, however, is dependent on the supposition that colchicine would in no way influence the process of replication at the X_2 interphase. In an initial experiment we therefore dispensed with its use. Seedlings of *V. faba*, with lateral roots, were grown at a temperature of 20° C. in separate containers in tap-water to which thymidine-^{3}H (supplied by Messrs. Schwartz, Inc., New York) was added. Each plant received 25 µc. and the plants were transferred to pure tap-water after 12 hr. Roots were fixed after, 4, 6, 12, 24 and 48 hr. and autoradiographs of squash preparations were prepared by the stripping film technique. The 4-, 6- and 12-hr. samples were considered necessary for comparison with earlier data obtained[4] in *V. faba* with phosphorus-32.

Very few mitotic figures were labelled in the roots fixed after 12 hr., and then only weakly. In roots fixed after both 24 and 48 hr. the autoradiographs were found to be labelled along the length of both chromatids over most metaphase chromosomes (Fig. 1*a*), and also along both daughter chromatids at anaphase (Fig. 1*b*). In the sample fixed after 48 hr., however, some chromosomes with singly labelled chromatids occurred in 12 per cent of the metaphases.

It was necessary to have criteria for distinguishing the X_1 and X_2 mitoses after labelling. The proportion of interphase nuclei labelled at 4, 24 and 48 hr. is only 20–25 per cent and it can be concluded that the labelled compound is used up after approximately one-quarter of the mitotic cycle (6 hr.). This excludes the possibility of additional labelling during the second period of synthesis of deoxyribonucleic acid and on average the nuclei at the X_2 mitosis should contain half the tracer found at X_1. After 48 hr. 16 per cent of the metaphases were heavily labelled and can be regarded as X_1 mitoses; a similar proportion of X_1 and X_2 metaphases were found after 48 hr. in a later experiment in which colchicine was used. The average duration of the mitotic cycle in the root meristem of *V. faba* has been found by various methods to be about 24 hr.[4,5], and very few X_1 mitoses would be expected after 48 hr. Synthesis of deoxyribonucleic acid lasts for 6–8 hr. and the division 1 hr. after an intervening period of about 8 hr.[4]. It can therefore be expected that no more than one-fifth of the labelled metaphases at 48 hr. were X_1.

It was concluded that the results obtained by Taylor and his collaborators were due largely to the extended treatment with colchicine and especially to the fact that only the X_2 period of chromosome replication took place in the presence of this agent. It seemed possible that chromosomes with singly labelled chromatids might be obtained at the X_1 mitosis by pre-treatment of the roots with colchicine.

Seedlings grown as described before were transferred to tap-water containing a concentration of 0·05 per cent colchicine to which thymidine-^{3}H was

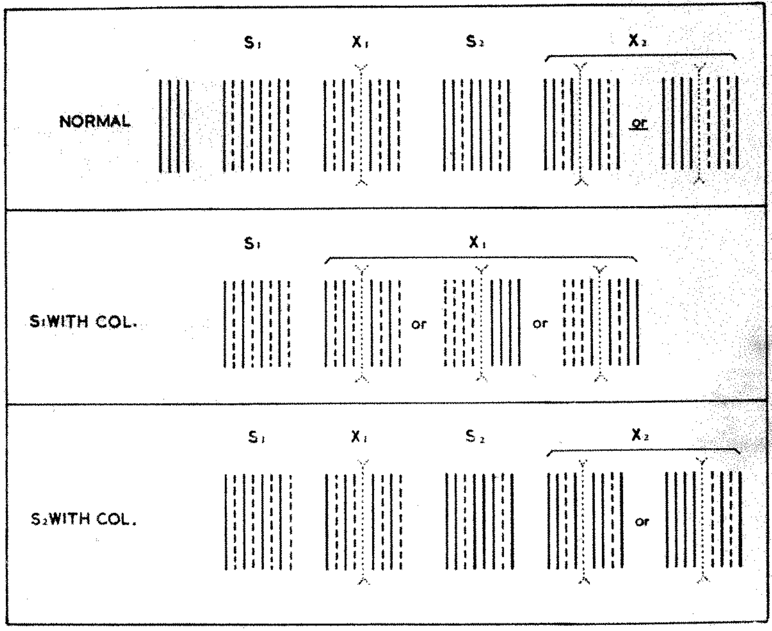

Fig. 3. Scheme of chromosome reproduction assuming four strands before replication. It is assumed that labelled thymidine is available at the first period of synthesis (S_1) but not during the second (S_2) and that colchicine (*col*) influences the segregation of new and old strands, possibly by an effect on the centromere. In the absence of colchicine the alternative (*or*) at X_2 is considered a rare possibility, but this might perhaps explain the results of Plaut and Mazia (ref. 7) with thymidine-^{14}C in *Crepis capillaris* if it is assumed that the duration of the mitotic cycle is shorter than in *Vicia* or that the number of strands is different. Strands figured as broken lines are those containing thymidine-^{3}H

added 1 hr. later. This was replaced after 8 hr. by fresh tap-water with colchicine, and roots were fixed after 20 and 24 hr.

In both samples the *C*-metaphases contained some chromosomes labelled along the length of both chromatids and some only along the length of one (Fig. 2*a* and *b*). So far as could be seen, very few *C*-metaphases showed all the 12 chromosomes with labelling in both chromatids. Furthermore, closely similar results to these were obtained in X_2 metaphases when we repeated the experiment of Taylor and his collaborators. Complete analysis in tetraploid cells was more difficult, but many *C*-metaphases clearly contained a few chromosomes labelled along the length of both chromatids in addition to those labelled only in one. These observations conflict with those of Taylor *et al.*, and it is justifiable to assume that colchicine can markedly alter the results obtained.

In the presence of a labelled precursor, self-reproduction of deoxyribonucleic acid based on the Watson and Crick model should result in labelled molecules and therefore should never lead to one chromatid of a chromosome being unlabelled at the X_1 mitosis. As a working hypothesis, for which cytological evidence is available[6], it is worth while considering that the chromosome may be multiple-stranded at the time of reproduction. If it is assumed that each chromosome consists of four strands before duplication (Fig. 3) and that each chromatid after replication usually consists of two new and two old strands, then the appearance of equally labelled chromatids at both the X_1 and X_2 mitosis would be expected. If it is further assumed that colchicine could influence the segregation of new and old strands, and hence the distribution of new and old deoxyribonucleic acid, then a situation as envisaged in Fig. 3 could arise. This working hypothesis can be checked experimentally with thymidine-^{3}H and possibly most simply in the absence of colchicine. If this is correct, for *V. faba* at least, grand-daughter cells (X_2) from the labelled X_1 should contain chromosomes with one labelled and one unlabelled chromatid.

Some other facts that are likely to affect interpretation in further studies were noticed in our experiments. Occasionally, both in X_1 and X_2 metaphases, labelled and unlabelled chromosomes occurred together in the same cell and twice an *M*-chromosome was found labelled in only one arm. This kind of disparate labelling appears to be confined to weakly labelled cells and suggests that not all the chromosomes in a cell are replicated exactly at the same time. It would become apparent in cells which had undergone synthesis when the store of labelled compound was near depletion, or where the chromosomes had nearly completed reproduction when the label became available. Also, at interphase, small parts of labelled nuclei may show absence of autoradiographs. In many cells this is clearly associated with heterochromatic regions and suggests that these may be replicated at a different time from the euchromatic portions of the chromosomes. Occasionally, however, the interphase nuclei show a similar absence in other chromosome parts. Therefore, the possibility cannot be ignored that sometimes in some parts of the chromosomes the labelled thymidine may perhaps be replaced after synthesis by unlabelled thymidine. No instance of somatic crossing-over was observed, but this possibility must also be considered.

CONDITIONAL ANTI-MUTAGENESIS IN *DROSOPHILA MELANOGASTER*

By DR. THOMAS ALDERSON

Institute of Animal Genetics, University of Edinburgh

IN a previous communication[1], I have reported that adenine produces a significant depression of the mutagenic activity of formaldehyde when both compounds are simultaneously present in the food of developing *Drosophila melanogaster* larvæ. The experiment leading to this observation was based on the working hypothesis that formaldehyde is effective as a mutagen by the larval feeding method, by competing with the normal (formic acid) metabolite in purine biosynthesis. The addition to the test system of preformed purine, in this case as adenine, is believed to decrease the mutagenic activity of formaldehyde by 'by-passing' the biosynthetic sequence through which formaldehyde is assumed to act. The present communication describes a further observation on the anti-mutagenic activity of adenine towards formaldehyde, consistent with this hypothesis.

The culture medium and methods used are as previously described[1]; Distillers' Co., Ltd., yeast was the yeast employed in the treatment medium.

Curves *a* and *b*, Fig. 1 (see Table 1), illustrate respectively the first and second brood response of the percentage of sex-linked recessive lethal mutations to the concentration of formaldehyde in the treatment medium. The first brood response shows an increase with increasing formaldehyde concentrations, becoming asymptotic at approximately $3 \cdot 0 \times 10^{-2}$ *M*. From the hypothesis, it might therefore be assumed that the response of the first brood to increasing concentrations of formaldehyde (Fig. 1, curve *a*) represents a measure of the extent to which formaldehyde interferes in purine synthesis, the response becoming asymptotic when formaldehyde is saturating the system. The second brood response increases up to approximately $2 \cdot 0 \times 10^{-2}$ *M* form-

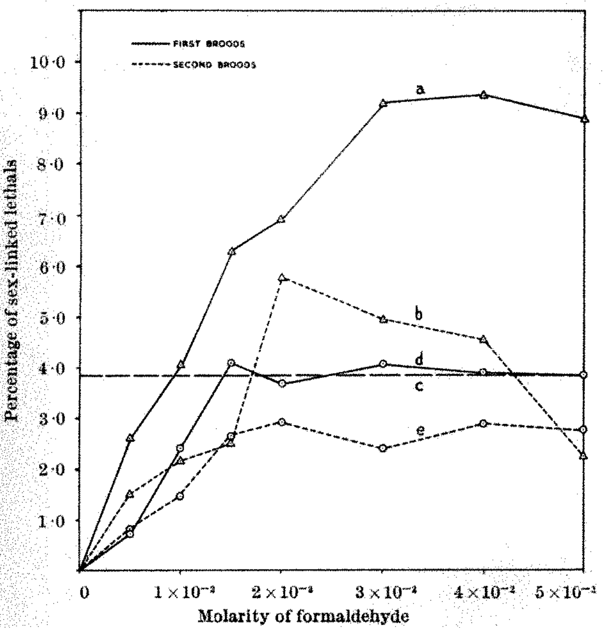

Fig. 1. Anti-mutagenic effect of adenine towards formaldehyde at different concentrations of formaldehyde. Curves *a* and *b* represent respectively the dose–mutagenic response for formaldehyde of the first and second brood; *d* and *e* their response in the presence of the antimutagen, adenine

aldehyde, but falls off at higher concentrations; this latter effect is thought to be due to the increased toxicity of the treatment at the higher concentrations. For the purpose of discussion, it is convenient to consider only the first brood response, owing to the irregularity of response in the second brood.

In the case previously reported[1], the addition of 0·09 per cent adenine ($6 \cdot 6 \times 10^{-3}$ *M*) to the test medium reduced the mutagenic activity of formaldehyde from 9·72 per cent to 3·37 per cent sex-linked lethals in the first brood, where 0·4 per cent (4×10^{-2} *M*) formaldehyde was used as the test concentration. Thus one might conclude, *ex hypothesi*, that the actual decrease in the mutagenic effectiveness of formaldehyde is due to a corresponding decrease in purine synthesis, produced by the addition of adenine; this decrease is represented by the difference in value recorded for $4 \cdot 0 \times 10^{-2}$ *M* formaldehyde on curve *a* from that indicated by line *c* (Fig. 1). A reduction of purine synthesis to the level indicated by line *c* is therefore anticipated when this amount of adenine is added to the test medium.

Accordingly, if the formaldehyde concentration is varied by attenuated dosage over the range recorded in the dose-effect curve, the concentration of adenine itself being kept constant at $6 \cdot 6 \times 10^{-3}$ *M*, a concentration of formaldehyde will be reached (which one might take tentatively as approximately $1 \cdot 0 \times 10^{-2}$ *M*, see Fig. 1), at which adenine should show no anti-mutagenic effect; this is because the amount of formaldehyde present is at a level with, or less than, that to which purine synthesis is reduced. Thus, one might expect that the anti-mutagenic effectiveness of adenine towards formaldehyde will decrease as the concentration of formaldehyde decreases, until the point is reached at which it might be allowed that the anti-mutagenic effect disappears; at this latter point, and over the sensitive range of formaldehyde concentrations, the mutagenic activity of formaldehyde should therefore be reduced to the level delineated by line *c* (Fig. 1). These conjectures form the basis for the experiments reported here.

In anticipation of the objection that formaldehyde might be removed from the treatment medium by simple chemical combination with adenine, a test was carried out *in vitro* for detection of the extent to which formaldehyde and adenine combine chemically, using the methone method for gravimetric estimation of formaldehyde[2]. At concentrations of $4 \cdot 0 \times 10^{-2}$ *M* formaldehyde and $6 \cdot 6 \times 10^{-3}$ *M* adenine, a reduction in formaldehyde concentration to $3 \cdot 5 \times 10^{-2}$ *M* was detected, which as can be seen by reference to the dose-effect curve (Fig. 1, curve *a*) would have no appreciable effect on the percentage of lethals produced. Indeed, if the anti-mutagenic activity of adenine was one simply involving removal of formaldehyde from the treatment medium by its chemical combination with adenine, the anti-mutagenic activity would be expected to increase with decreasing formaldehyde concentration, since the removal of formaldehyde would be more effective at the lower concentrations. It follows from the working hypothesis that the chemical removal of formaldehyde by adenine is only a consideration at concentrations of formaldehyde actually below that to which purine synthesis is reduced, since at higher concentrations the actual concentration of formaldehyde would be greater than its effective concentration.

Thus Table 2 formulates the results obtained from testing the anti-mutagenic activity of adenine at different concentrations of formaldehyde; these results are illustrated graphically for first and second broods by curves *d* and *e*, respectively (Fig. 1). In the first brood, the mutagenic effectiveness of form-

aldehyde for all concentrations above approximately $1 \cdot 5 \times 10^{-2}$ *M* formaldehyde is seen to be depressed down to the level postulated. The second brood follows essentially the same pattern, but is depressed lower than in the first brood; this may be because the normal brood gradients for the mutagenic activity of formaldehyde (curves *a* and *b*) involve different levels of purine synthesis, so that, in effect, adenine is able to depress purine synthesis more effectively in the second brood. At concentrations of formaldehyde below $1 \cdot 5 \times 10^{-2}$ *M*, the anti-mutagenic effect of adenine in both broods is much less apparent, and here may be accounted for simply by removal of formaldehyde by chemical combination with adenine. Third broods were sampled at $1 \cdot 0 \times 10^{-2}$ *M* and $3 \cdot 0 \times 10^{-2}$ *M* formaldehyde. Usually, the mutation-rate has returned to the spontaneous level by the third brood, but as can be seen from Tables 1 and 2, some mutagenic activity is still detectable. A slight anti-mutagenic trend can also be observed here.

As previously reported[1], the anti-mutagenic activity of adenine towards formaldehyde is conditional on the strain (and concentration) of yeast employed in the culture medium. The present communication describes a further case of conditional anti-mutagenesis; namely, the concentration of the mutagen at which anti-mutagenic activity is tested.

I wish to acknowledge financial support from the Medical Research Council, under the auspices of which this work was carried out.

FRACTIONATION OF CELL SUSPENSIONS IN AN ELECTROMAGNETIC FORCE FIELD

By Prof. ALEXANDER KOLIN and RAYMOND T. KADO
Department of Biophysics, University of California, Los Angeles

THE effectiveness of centrifugation as a method of fractionation of aqueous suspensions of cells and of cell debris is limited by the fact that the densities of these biological materials differ but little from each other and from the density of the suspension fluid. The effective electrical conductivities of cells, on the other hand, vary widely, sometimes by two or three orders of magnitude. A method of fractionation based on differences in electrical conductivites, rather than in densities, of suspended particles would therefore be of interest. The possibility of developing such a method is suggested by an effect recently described by one of us[1]. It has been shown that a spherical particle of conductivity σ' suspended in a fluid of conductivity σ'' experiences a force when a homogeneous current is passed through the suspension across which a homogeneous magnetic field is maintained preferably at right angles to the current. The force is perpendicular to the magnetic field and the current and is given by the expression:

$$\mathrm{F} = \frac{3}{2} V \left(\frac{\sigma'' - \sigma'}{2\sigma'' + \sigma'} \right) [\mathbf{J} \times \mathbf{B}] \qquad (1)$$

where V is the volume of the sphere, **J** the current density and **B** the magnetic flux density[2]. This force is seen to vanish for $\sigma'' = \sigma'$ and to reverse direction for $\sigma' > \sigma''$.

The velocity of a spherical particle of radius R in a fluid of viscosity η is given by the expression:

$$v = \frac{R^2}{3\eta} \left(\frac{\sigma'' - \sigma'}{2\sigma'' + \sigma'} \right) [\mathbf{J} \times \mathbf{B}] \qquad (2)$$

This equation suggests the possibility of separating particles on the basis of differences in R and in σ'.

To obtain unidirectional migration, it is not necessary to use unidirectional currents and constant magnetic fields. This result may be also obtained by using alternating magnetic fields and currents in

Fig. 1*b*. Light path L (indicated by broken line): E_1, E_2, electrodes; Pr_1 and Pr_2, prisms; J, current density vector; B, magnetic field vector; PL, projection lens

Fig. 1*c*. Migration cell in the magnetic field: W_1 and W_2, magnet coils; P_1 and P_2, pole pieces (P_2 is depicted cut-away to show the cell); C, migration cell; C_1 and C_2, adjustment coils; R, support rod; L, electrode lead wires; CL, lead wires for coils C_1, C_2

phase. The use of alternating currents greatly simplifies the design of the migration cell which is shown in Fig. 1*a*. The current **J** is passed between the parallel metal electrodes E_1, E_2. The other two parallel walls of the migration channel of the cell are made of 'Lucite'. Light enters the migration channel after reflexion inside the prism Pr_1. It traverses the cell parallel to the magnetic field vector B and hits a prism Pr_2 (shown in Fig. 1*b*) mounted parallel to Pr_1 on the opposite side of the cell. The 45 deg. surface of Pr_2 is oriented so as to reflect the light parallel to and in the same direction as L_1. A projection lens PL located beyond Pr_2 (Fig. 1*b*) forms an image of the interior of the migration channel on a distant screen. Fig. 1*c* shows the cell placed between the pole pieces P_1 and P_2 of the magnet. The plug P, shown above the cell in Fig. 1*a*, is inserted into the migration channel after the cell is filled. This plug is provided with a narrow channel O for escape of surplus liquid. The vector **F** indicates the direction of the force exerted upon the suspended particles for $\sigma' > \sigma''$ and, hence, the direction of migration. C_1 and C_2 (Fig. 1*a*) are coils wound about the migration cell. They facilitate adjustment of the cell at right angles to the magnetic field. When the cell is properly oriented the electromotive force induced in the coils C_1 and C_2 vanishes.

Two experimental difficulties must be eliminated before successful fractionation of suspensions can be accomplished: (1) the thermal convection caused by a horizontal temperature gradient established by passage of a current through the cell must be eliminated; and (2) the electromagnetic convection[3] caused by non-uniformities in the magnetic field and/or in the current density distribution in the fluid column must be suppressed. The horizontal temperature gradient is associated with a horizontal density gradient which upsets the gravitational equilibrium in the fluid column. The effect produced by a non-uniformity in the magnitude of $[\mathbf{J} \times \mathbf{B}]$ at right angles to the **F**-axis is analogous, since the force density $\mathbf{f} = [\mathbf{J} \times \mathbf{B}]$ is the counterpart of the weight density in the case of gravitational equilibrium.

Both types of convection can be effectively inhibited by establishing a steep density gradient in the migration column. This device has been previously used successfully for suppression of thermal convection in electrophoresis[4]. An adequate density gradient can be produced by filling the lower half of the cell with a 5 per cent solution of sodium chloride containing 46 gm. of sucrose per 100 ml. of solution and the upper half with 1·3 per cent sodium chloride solution. The density gradient is established by stirring the liquid column.

A droplet of the suspension to be fractionated is now injected into the density gradient. It settles at the density-level corresponding to its own density. Fluid is then withdrawn from this level by micropipette to create a density discontinuity. A small amount of the suspension (the density of which is adjusted to the value of the density of the withdrawn fluid) is now carefully injected at the level of the density jump so as to create a thin sharp zone. The conductivity of the suspension is adjusted approximately to the value of the conductivity of the density

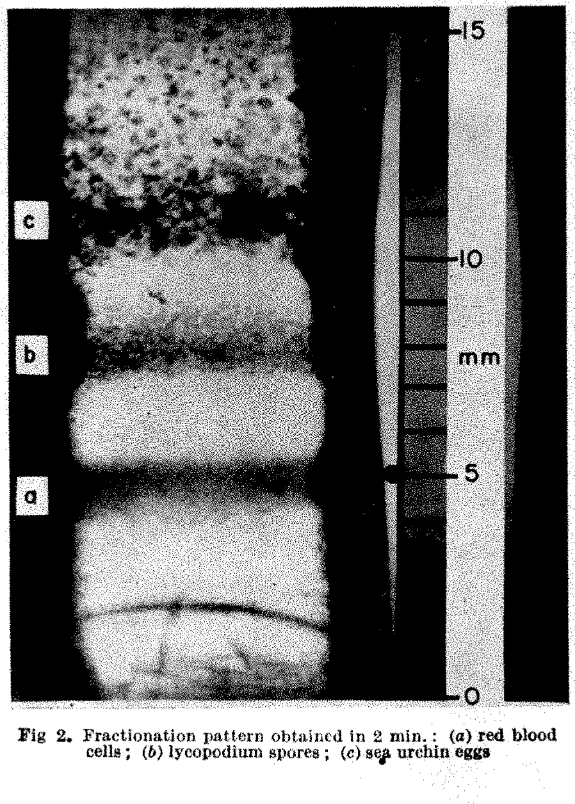

Fig 2. Fractionation pattern obtained in 2 min.: (*a*) red blood cells; (*b*) lycopodium spores; (*c*) sea urchin eggs

gradient column. When the magnetic field and current are turned on, the particles suspended in the initial zone begin to migrate with different speeds and the zone finally splits into separate zones containing the different components of the mixture.

Fig. 2 shows a fractionation which was accomplished within approximately 2 min. The mixed suspension contained (*a*) red blood cells ($R \simeq 4\,\mu$), (*b*) lycopodium spores ($R \simeq 15\,\mu$) and (*c*) sea urchin eggs ($R \simeq 60\,\mu$). The thin curved black line below the *a*-zone depicts a steep refractive index gradient formed by convection near the bottom of the cell. The magnetic field $\mathbf{B} \simeq 6{,}000$ gauss (root mean square value) and the current density $\mathbf{J} \simeq 100$ m.amp./cm.^{2}. The temperature rise in the liquid during this time amounted to $\Delta t \simeq 5°$ C. The frequency of the field used was 60 c./s.

It has been shown that this effect can also be produced in a cylindrically symmetrical configuration[5]. In this case the magnetic field of a straight wire is used in combination with an electric current parallel to the wire. The force field thus generated is centripetal or centrifugal, depending on the phase relation between **B** and **J**. This arrangement offers the prospect of centrifugation without rotational motion.

SIGNIFICANCE OF INDUCED *IN VIVO* SYNTHESIS OF DIPHOSPHOPYRIDINE NUCLEOTIDE

By DR. LOUIS SHUSTER, THOMAS A. LANGAN, jun.*, PROF. NATHAN O. KAPLAN and PROF. ABRAHAM GOLDIN

Graduate Department of Biochemistry, Brandeis University, Waltham, Massachusetts, and
The Laboratory of Chemical Pharmacology, National Cancer Institute, The National Institutes of Health,
Bethesda, Maryland

THE observation that the injection of nicotinamide into mice can produce large increases in the amount of diphosphopyridine nucleotide in the liver[1] has facilitated the *in vivo* study of many interesting biochemical problems. A description of some of the results which have been obtained, and a discussion of possible further applications of this system, are presented here.

Nature of Diphosphopyridine Nucleotide Synthesis

Extent of synthesis. The increase in diphosphopyridine nucleotide following the injection of nicotinamide is temporary, and is roughly proportional to the dosage of nicotinamide up to a level of 500 mgm. per kgm. With this dose the diphosphopyridine nucleotide content of mouse liver reaches a level of 8 – 10 times the base value of 400 – 500 μgm. per gm. wet weight at about 10 hr., then returns to normal at the end of 24 hr. Two- to three-fold increases in the diphosphopyridine nucleotide content of other tissues such as kidney, spleen and tumour also occur. Oxidized diphosphopyridine nucleotide accounts for almost all the increase in pyridine nucleotides following the administration of nicotinamide. Attempts to show an accumulation of diphosphopyridine nucleotide by incubating liver slices or fortified homogenates with nicotinamide have been unsuccessful.

Pyridine precursors. The initial observation of a marked increase in diphosphopyridine nucleotide content of mouse liver was made after the administration of the nicotinamide antagonist 3-acetylpyridine[2]. When similar results were obtained with nicotinamide it became clear that acetylpyridine was being converted to nicotinamide *in vivo*. The conversion of an anti-metabolite to a metabolite in this instance can be considered as a type of detoxification mechanism.

A number of other pyridine derivatives, such as β-picoline, can also act as precursors of diphosphopyridine nucleotide in the whole animal[3]. The effectiveness of these compounds in producing synthesis of diphosphopyridine nucleotide can be correlated with their ability to replace nicotinamide in the diet of the duckling[4]. Of special interest is the observation that nicotinic acid is much less effective than nicotinamide as a precursor, and can even inhibit the conversion of nicotinamide to diphosphopyridine nucleotide[3].

Effect of diphosphopyridine nucleotide synthesis on the chemical composition of mouse liver. The biosynthesis of diphosphopyridine nucleotide stimulated by nicotinamide is reflected as an increase in the

Table 1. CHANGE IN SOME ACID-SOLUBLE CONSTITUENTS OF MOUSE LIVER FOLLOWING THE ADMINISTRATION OF NICOTINAMIDE

	μmoles per gm. wet weight	
	Control	Nicotinamide injected
Diphosphopyridine nucleotide	0·79	5·74
Total nicotinamide	0·73	5·99
Adenine	3·8	8·4
Ribose	12·9	20·4
Total phosphate	48·2	59·4

Analyses were carried out on a 5 per cent trichloracetic acid extract prepared from the livers of mice killed 8 hr. after the administration of 500 mgm. per kgm. of nicotinamide. Controls were injected with saline. Adenine was determined by the colorimetric method of Woodhouse (ref. 5), which gave results in good agreement with values calculated from the increase in optical density at 260 mμ (ref. 1). Total nicotinamide was determined by the Holman method (ref. 6) after boiling at 100° for 30 min. (*p*H 7·8). The values represent the pooled samples of four mice in each group.

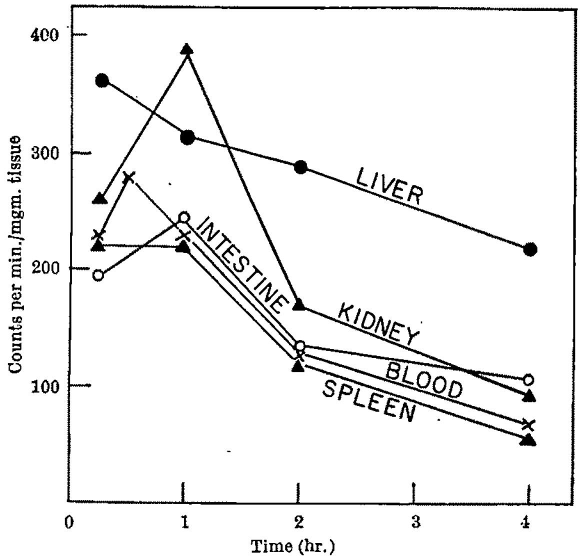

Fig. 1. The uptake of radioactivity by various organs of mice injected with labelled nicotinamide. Mice were injected intraperitoneally with 500 mgm. per kgm. of labelled nicotinamide (approximately 8×10^6 counts per minute per animal). The values for blood are counts per minute per 0·001 ml. whole blood. Radioactivity in other tissues was determined after dissolving the organs in boiling formamide

total acid-soluble nicotinamide, adenine, ribose and organic phosphate of mouse liver (Table 1). These changes are in good agreement with the increase in diphosphopyridine nucleotide. No change in adenosine phosphates or nucleic acid content of the liver has been detected.

These observations indicate that formation of diphosphopyridine nucleotide does not occur at the expense of adenine, ribose and phosphate already present in the liver. Rather, there must be either mobilization from extra-hepatic sources, or actual net synthesis of the required moieties.

Incorporation of Labelled Precursors

Incorporation of nicotinamide. This system has provided an unusual opportunity for detecting intermediates in the conversion of nicotinamide to diphosphopyridine nucleotide under *in vivo* conditions. The specific activities of some mouse tissues following the injection of nicotinamide labelled at its carboxyl group with carbon-14 are shown in Fig. 1. The relatively constant level of radioactivity in the liver while rapid synthesis of diphosphopyridine nucleotide is taking place suggests the presence of precursors. One of the radioactive compounds detected in the liver early in the synthesis has been identified as free nicotinamide. Another has been identified as the nicotinic acid analogue of diphosphopyridine nucleotide[7]. Forty-five minutes after the injection of labelled nicotinamide the specific activity of the analogue was twice as high as that of diphosphopyridine nucleotide. The analogue is present in the liver in largest amounts during the time the diphosphopyridine nucleotide is being synthesized, and in small amounts during the subsequent period of diphosphopyridine nucleotide degradation. These observations[8] indicate that the nicotinic acid analogue or possibly a labile carboxyl derivative of the analogue is an intermediate of the synthesis of diphosphopyridine nucleotide from nicotinamide. Preiss and Handler[9] have shown that the analogue is an intermediate in the *in vitro* synthesis from nicotinic acid by erythrocytes. Nicotinamide is a relatively inefficient precursor, the principal product formed being nicotinamide mononucleotide. In the whole mouse, however, nicotinic acid is a poor precursor, and an inhibitor of the formation from nicotinamide of both analogue and diphosphopyridine nucleotide. Removal of the amide group already present in nicotinamide during its conversion to diphosphopyridine nucleotide might indicate a requirement for a carboxyl substituted pyridine nucleotide as an intermediate at some step in the synthesis.

Incorporation of glucose. Evidence for an accelerated conversion of glucose to ribose during the biosynthesis of diphosphopyridine nucleotide has been obtained in experiments where glucose labelled with carbon-14 was administered together with nicotinamide[10]. The incorporation of ribose labelled similarly was also stimulated by nicotinamide. There was an increase in the specific activity of the ribose of both diphosphopyridine nucleotide and free adenylic acid. Incorporation into the nicotinamide ribose moiety of diphosphopyridine nucleotide was considerably greater than into the adenine ribose. When labelled glucose alone was administered, incorporation into the nicotinamide ribose of the endogenous diphosphopyridine nucleotide was also greater than into the adenine ribose, indicating a more rapid turnover of the nicotinamide ribose than the adenine ribose in the normal animal. As yet it is difficult to explain these results in terms of known enzymatic mechanisms.

The rapid conversion of glucose to ribose during the induced biosynthesis of diphosphopyridine nucleotide makes this system useful for studying pentose formation in the whole animal. Experiments in which differentially labelled glucose was administered with nicotinamide[11] have shown that in mouse liver not more than 5 – 10 per cent of the diphosphopyridine nucleotide ribose is formed by oxidative decarboxylation and that pentose synthesis can be explained largely in terms of the transaldolase–transketolase pathway[12].

Incorporation of phosphate. Administration of nicotinamide at 500 mgm. per kgm. stimulated fourfold the incorporation of inorganic phosphate labelled with phosphorus-32 into the diphosphopyridine nucleotide of mouse liver[8]. In contrast to the results with labelled glucose, there was no preferential incorporation into the nicotinamide phosphate of diphosphopyridine nucleotide.

Incorporation of adenine and its precursors. Nicotinamide administration stimulated slightly the incorporation of adenine-8-^{14}C into diphosphopyridine nucleotide without affecting incorporation into free adenylic acid. The incorporation of both glycine-2-^{14}C and formate-^{14}C into diphosphopyridine nucleotide, free adenylic and nucleic acid adenine was stimulated as much as five- to ten-fold by nicotinamide when incorporation was measured over a 1-hr. interval. When formate incorporation was measured over a 5-min. interval there was a fifteen-fold increase in specific activity of free adenylic acid but little change in the labelling of diphosphopyridine nucleotide. Nicotinamide had no effect on the incorporation of formate-^{14}C or glycine-2-^{14}C into liver protein.

When incorporation of formate, glycine, glucose and adenine was measured over successive half-hour intervals following injection of nicotinamide, the total incorporation of formate into diphosphopyridine nucleotide was found to increase, while the incorporation of other precursors either decreased or showed little change. This may indicate the occurrence of some exchange reactions.

The observation that the administration of nicotinamide can increase the incorporation of glucose, formate and glycine into free adenylic acid as well as into diphosphopyridine nucleotide suggests that there is actually a net synthesis of adenine and ribose rather than a transfer of these components into the liver for diphosphopyridine nucleotide synthesis. This should make the system synthesizing diphosphopyridine nucleotide useful for studying net purine synthesis over a short time period in the intact animal.

Metabolic Studies with altered *in vivo* Levels of Diphosphopyridine Nucleotide

Few studies of the effect of an elevated level of diphosphopyridine nucleotide in the liver on metabolism have yet been carried out. Smith *et al.*[13] have examined the effect of nicotinamide administration on ethanol metabolism in the whole mouse, in liver slices and in liver homogenates. The only difference observed was a two-fold increase in the rate of ethanol oxidation by liver homogenates prepared in a medium containing nicotinamide. They concluded that normal diphosphopyridine nucleotide-levels are adequate for ethanol oxidation in the whole animal or in liver slices, the limiting factor being enzyme concentration. In homogenates, where considerable destruction of endogenous diphosphopyridine nucleotide takes place by enzymes released from the tissue, increasing the diphosphopyridine nucleotide-content of the intact liver may help to maintain normal levels. We have found that the oxidation of formate-^{14}C to carbon dioxide in the whole mouse is also unaffected by nicotinamide administration.

Some Factors influencing Diphosphopyridine Nucleotide Synthesis

Effect of tumour growth. Waravdekar *et al.*[14] have reported that the growth of tumours in mice causes a decrease in the diphosphopyridine nucleotide content and diphosphopyridine nucleotide pyrophosphorylase activity of the blood. We have observed a 50 per cent reduction in the synthesis of diphosphopyridine nucleotide induced by nicotinamide (on a unit wet-weight basis) in the livers of mice bearing advanced leukæmia *L*-1210. This apparently reflected leukæmic infiltration and could be correlated with an increase in liver weight. There was actually little change in the amount of diphosphopyridine nucleotide synthesized per mouse. Treatment with amethopterin, which restored liver weights to normal, also restored synthesis. The growth of a number of solid tumours was found to have little effect on diphosphopyridine nucleotide synthesis in the liver.

Nicotinamide antagonists. These can affect the *in vivo* synthesis of diphosphopyridine nucleotide from nicotinamide in a number of different ways. Some pyridine derivatives, for example 3-acetylpyridine, are converted to nicotinamide in the body[2,3] and are capable of increasing the synthesis at low doses, or inhibiting it at high doses[3].

The effect on diphosphopyridine nucleotide synthesis of the nicotinamide antagonist 2-ethylamino-1,3,4-thiadiazole depends on the dose of nicotinamide. Inhibition was evident when the thiadiazole was administered with a high dose of nicotinamide, but with a low dose there was stimulation. These relationships may be of particular interest because the toxicity of the thiadiazoles and their anti-tumour activity can be prevented by nicotinamide[15,16] and thiadiazole can be incorporated into an analogue of diphosphopyridine nucleotide *in vitro*[16].

It is difficult to relate interference with diphosphopyridine nucleotide synthesis to toxicity. A single dose of one of the most potent nicotinamide antagonists, 6-amino nicotinamide, was not found to have any effect on this synthesis[3]. On the other hand, nicotinic acid, which is not generally considered to be a nicotinamide antagonist, was found to inhibit strongly the synthesis from nicotinamide[3].

Purine antagonists. The toxicity and antileukæmic action of 6-mercaptopurine can be prevented by administration of adenylic acid or a number of related compounds[17]. Diphosphopyridine nucleotide synthesis in mice is inhibited by 6-mercaptopurine and this inhibition can also be prevented by adenylic acid[1]. Similar results have been obtained with the purine antagonist thioguanine. In addition to decreasing the amount of diphosphopyridine nucleotide synthesized, these compounds also appear to interfere with the return of its levels to normal values at the end of 24 hr. following nicotinamide administration. In the case of 6-mercaptopurine this difference at 24 hr. can be as much as five-fold, and this effect of the drug is not reversed by adenylic acid[1].

Folic acid antagonists. The toxicity and antileukæmic action of aminopterin and amethopterin can be prevented by folic acid or some of its derivatives[18]. The folic acid antagonists are presumed to inhibit tumour growth by interfering with the biosynthesis of nucleic acids. Skipper *et al.* have reported decreased incorporation of formate-^{14}C into the nucleic acid purines of mice after treatment with aminopterin or amethopterin[19]. There have also been reports that such treatments actually stimulate *in vivo* incorporation of formate[20].

Amethopterin was found to have little effect on either the normal levels of diphosphopyridine nucleotide or upon *in vivo* synthesis following nicotinamide injection, even after extensive treatment. Similarly, experiments with mice bearing leukæmia *L*-1210 showed that this tumour retained its ability to synthesize diphosphopyridine nucleotide even while undergoing definite regression in size as a result of amethopterin treatment.

The incorporation of formate-^{14}C into mouse-liver diphosphopyridine nucleotide was found to be stimulated as much as eight-fold by treatment with amethopterin. Increased formate incorporation could be correlated with signs of toxicity such as weight loss, decreased leucocyte count and mortality. On a schedule of single daily treatments there was almost direct proportionality between the dose of amethopterin and formate incorporation (Fig. 2).

Increased formate incorporation into liver adenylic acid, nucleic acids and protein after amethopterin treatment could also be demonstrated when no nicotinamide was given. These observations may be related to the results reported by Barclay and Garfinkel[21]. They found that the incorporation of formate-^{14}C into liver proteins and nucleic acids was stimulated by treatment with N-methyl formamide, carbon tetrachloride or azaserine. They interpret this effect as a manifestation of hepatotoxicity.

Tranquillizing agents. The administration to mice of reserpine or promazine before the injection of

MACMILLAN BOOKS

The Economics of International Migration

EDITED BY *BRINLEY THOMAS*

Trends in international migration have been profoundly changed in the last thirty years by the American Restriction Act of 1924, the great depression of the early 1930's and the Second World War. Twenty-four papers on the subject by leading experts, and a record of the discussions of the seventh conference of the International Economic Association. 45*s*

Textbook of Economic Analysis

EDWARD NEVIN, M.A., PH.D.

An introduction to the groundwork of contemporary economic and monetary theory. Assuming no previous knowledge on the part of the reader, it sets out to explain the nature and scope of economic analysis, and then proceeds to an exposition of the modern theories of demand, supply, value and income distribution. Finally, the book deals with the issues arising from international transactions. 'With this book Dr. Nevin will earn the gratitude of many teachers, to say nothing of their students. It undoubtedly fills a gap in first-year reading lists.'—*Accountancy*.
With diagrams 18*s*

An Atlas of Airborne Pollen Grains

H. A. HYDE and K. F. ADAMS

This atlas is intended primarily as an aid to the identification of pollen grains in the fresh condition. The ninety-two species described are those which can be observed at a magnification of about 1,000 diameters. The book should be of value in studies of airborne pollen in general and in relation to hayfever, and, to a lesser degree, the pollen loads of bees, and pollen in honey and in peat. *Illustrated* 36*s*

General Microbiology

ROGER Y. STANIER, MICHAEL DOUDOROFF and EDWARD A. ADELBERG

This book attempts to present a modern synthesis of microbiological knowledge for university students of the biological sciences. Students new to this subject will find it particularly useful. *With photographs and diagrams* 50*s*

'BELLING-LEE'

Sub-Miniature

COAXIAL PLUGS & SOCKETS

The world of electronics is shrinking: miniaturisation is becoming the governing factor in many applications, enabling lighter and more compact equipment to do the work of standard installations.

"Belling-Lee" sub-miniature coaxial plugs and sockets are an example of our interest in miniaturisation, and indicative of the new developments in components which we shall be announcing from time to time.

We have also recently produced a range of printed circuit connectors and components, and three variations of miniature Unitor plugs and sockets. Full details of these are given in the Supplement to our General Catalogue (P.490), copies of which are available on request.

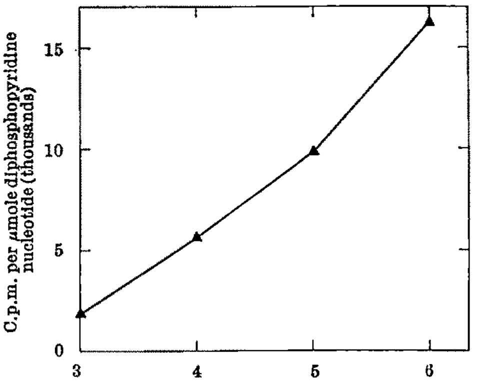

Fig. 2. Effect of daily treatment with amethopterin on the incorporation of formate-^{14}C into the diphosphopyridine nucleotide of mouse liver. Mice received daily subcutaneous injections of amethopterin for seven days. On the eighth day they were injected with 500 mgm. per kgm. of nicotinamide and formate-^{14}C. After 6 hr. the livers were homogenized with trichloracetic acid and the diphosphopyridine nucleotide isolated by ion-exchange chromatography

500 mgm. per kgm. of nicotinamide has little effect on the resulting increase in liver diphosphopyridine nucleotide, but prevents the return of its levels to normal at the end of 24 hr.[22]. High concentrations in the liver will then persist for as long as 48 hr. following the injection of nicotinamide. Whether this phenomenon results from some specific action upon the mechanisms which regulate the normal levels has yet to be resolved. When a number of reserpine derivatives were tested there was good correlation between their tranquillizing and anti-leukæmic effectiveness[23] and their ability to maintain the elevated level of diphosphopyridine nucleotide of liver following nicotinamide administration.

It is also of interest that reserpine will stimulate as much as ten-fold the incorporation of formate into the acid-soluble adenine of mouse liver. Such treatment has no effect on glycine incorporation or on the incorporation of formate into liver protein.

The investigations described here represent a few of the many fruitful ways in which diphosphopyridine nucleotide synthesis can be used to study biochemical mechanisms and the action of drugs in the whole animal.

This work was aided by grants from the National Cancer Institute, the National Institutes of Health (Grant *CY*-3611 Bio), the American Heart Association and the American Cancer Society.

AN INFECTIVE 'RIBONUCLEIC ACID' COMPONENT FROM TUMOUR CELLS INFECTED WITH ENCEPHALOMYOCARDITIS VIRUS

By J. HUPPERT

Chargé de Recherches C.N.R.S., Institut Pasteur, Paris

AND

F. K. SANDERS

Director, Virus Research Group, Medical Research Council

TREATMENT of tobacco mosaic virus with cold phenol gives preparations having up to 1 per cent of the original infectivity[1,2]; these are rich in ribonucleic acid, but contain too little virus protein to account for their infectivity. Since they are, moreover, highly unstable and can be rapidly inactivated by ribonuclease, it has been suggested that their infectivity is a property of ribonucleic acid released from the virus by phenol treatment[2], although this conclusion has been criticized on chemical grounds[3]. Phenol extracts of cells and tissues infected by several animal viruses have been shown to possess infectivity[4–6]. However, it is not clear (1) that the low infectivity is not due to residual intact virus; (2) that the infective material in phenol extracts comes from virus as such, and not from some other component of the infected tissue; or (3) that the infectivity is due to virus ribonucleic acid. Phenol extracts of infected cells will contain so much cellular ribonucleic acid that a minor non-ribonucleic acid component with virus activity might well escape detection.

We have been working with an *in vitro* and *in vivo* animal virus/host-cell system which may help to answer these questions. The first results reported here suggest that the infective material found in the aqueous phase following phenol extraction has properties which distinguish it from normal virus. Moreover, this material appears to come from some component of the infected tissue other than the virus itself.

Murine encephalomyocarditis virus is able to multiply to high titre in cells of the Krebs 2 mouse ascites carcinoma, maintained *in vitro* as continuously agitated cell suspensions[7]. With multiple infection (cells 10^7/ml.; virus 3×10^7/ml.) new virus first appears intracellularly about 4 hr. after infection, and reaches a maximum at 8 hr. Release of virus from a population of infected cells, beginning at 6–7 hr. after infection, occurs at a maximum rate between 9 and 11 hr. after infection, and is complete by 12 hr. The supernatant fluid then contains[8] about 1×10^9 plaque-forming units of virus per ml., and the same number of mouse ID_{50} when titrated *in vivo*.

Phenol extracts made either from culture fluids harvested at the peak of virus release (12–14 hr.), or from infected cells at various stages of the growth cycle, have demonstrable infectivity. Extractions were carried out at 4° C. by the method of Schuster *et al.*[9], and the preparations—henceforth termed 'ribonucleic acid extracts'—stored at − 70° C. Their infectivity for Krebs 2 carcinoma cells was tested in two different ways. (1) The ability of the material to infect static, non-dividing cells was tested by a plaque method of titration, using tumour cells suspended in agar[8]. (2) The activity of the material in a population of growing cells was tested by mixing it with suspensions of tumour cells, and injecting samples of 10^7 cells intraperitoneally into each of five mice per dilution. The encephalomyocarditis infectivity end-point was calculated by standard methods.

Table 1

Starting material	Virus content of starting material (plaque-forming units/ml.)	Infectivity of ribonucleic acid extract	
		By plating (plaque-forming units/ml.)	By mouse titration (MID_{50}/ml.)*
Supernatant from 14-hr. infected culture	2×10^9	45	4×10^4
		50	3×10^4
		30†	6×10^3
		20†	1×10^3
		400	5×10^4
		600	3×10^4
Infected cells			
2 hr.	1×10^6	5	10
4 hr.	$2{\cdot}8 \times 10^7$	125	5×10^3
8 hr.	$2{\cdot}2 \times 10^8$	95	3×10^3

* MID_{50}/ml., mouse infective doses/ml.
† Ethanol precipitated preparation.

Ribonucleic acid extracts made in the way described contained 5–600 plaque-forming units/ml. when plated on Krebs 2 cells (Table 1). The plaques formed appeared identical with those of the parent virus, and virus re-isolated from them had the expected properties. However, the plaque count for ribonucleic acid extracts in general did not diminish linearly with dilution, as already noted for eastern equine encephalomyelitis virus[5]. Plaque titration appears to measure the number of cells in the cell suspension used for titration which are 'competent' to take up active material from the ribonucleic acid extracts and make virus from it, rather than to estimate the total number of infective fragments present in the extract. This is borne out by the much higher titre shown by ribonucleic acid extracts when they are mixed with cells and titrated in mice (Table 1). Presumably a much higher proportion of cells become 'competent' under these conditions and are consequently able to produce virus. Further investigations of this cellular competence phenomenon will be reported in a later publication. Even when titrated in mice, ribonucleic acid extracts invariably had a titre much lower than that of the virus preparation from which they were made (Table 1).

The ultra-violet absorption spectra of ribonucleic acid extracts were measured in a 'Unicam' spectrophotometer. All preparations had a marked absorption peak at 260 mμ and a minimum at 240 mμ; the ratio of the adsorptions $\lambda_{260}/\lambda_{280}$ varied from 1·6 to more than 2. The concentration of ribonucleic acid was of the order of 2 mgm./ml. in terms of a commercial standard. All preparations tested appeared to contain some protein (20–150 μgm./ml.), but, since the Folin–Ciocalteu phenol reagent was used[10], these figures are presumably affected by any residual phenol present in the preparations, and their actual protein content may be much lower. All preparations, however, contained an enormous excess of cellular nucleic acid, mostly unrelated to the virus, so that chemical methods could not be used to show that the infectivity found belonged to viral ribonucleic acid alone and not to traces of other materials.

The infective material present in phenol extracts was, however, unlikely to be residual virus which had somehow escaped the inactivating effect of phenol. The infectivity of phenol extracts of mengo encephalitis and eastern equine encephalomyelitis viruses is destroyed by ribonuclease, and by incubation at 37° C., both treatments having relatively little effect on intact virus[4–6]. The infectivity of phenol extracts, moreover, can be precipitated with ethanol or 1 *M* sodium chloride, while that of virus is not so precipitated[5,6]. However, in some of the experiments already reported[4,6], the virus and ribonucleic acid preparations were not compared at equivalent levels of infectivity. Moreover, a possible 'protective' effect on virus of the large excess of normal cell ribonucleic acid in the phenol extract has not been considered. We have therefore tried to make comparison between an infective ribonucleic acid extract and encephalomyocarditis virus under as similar conditions as possible. Results are given in Table 2.

A phenol extract has been compared with encephalomyocarditis virus diluted to give a comparable plaque count; sufficient of a phenol extract of uninfected cells was added to the latter to give both preparations the same ultra-violet absorption at 260 mμ. Treatment with ribonuclease (10 μgm./ml.)

Table 2. COMPARISON OF PROPERTIES OF INFECTIVE RIBONUCLEIC ACID AND ENCEPHALOMYOCARDITIS VIRUS

Sample	Ribonucleic acid extract (MID_{50}/ml.)	Encephalomyocarditis virus (MID_{50}/ml.)
Control	3×10^2	1×10^3
After ribonuclease	0	$2{\cdot}5 \times 10^3$
After 1 hr. at 37° C.	10	7×10^2
After 1 hr. at 37° C. + 5 per cent rabbit serum	10	5×10^2
After 1 hr. at 37° C. + 0·1 per cent bovine plasma albumin	10	7×10^2
Sediment from ethanol precipitation (3 ×)	7×10^2	30
Sediment from precipitation with 1 *M* NaCl (3 ×)	$1{\cdot}6 \times 10^2$	70
	Ribonucleic acid extract (plaque-forming units/ml.)	Encephalomyocarditis virus (plaque-forming units/ml.)
Plating on normal cells (1)	20	120
(2)	20	
Plating on irradiated cells (1)	7×10^2	110
(2)	3×10^2	

for 15 min. at room temperature completely destroyed the infectivity of the ribonucleic acid extract, whereas that of the virus control was unaffected. Incubation at 37° C. for 1–1½ hr., either in the presence or absence of protein, reduces the titre of the ribonucleic acid preparation more than ten-fold, while that of the virus is only slightly affected. The ribonucleic acid extract can be precipitated and washed three times with 67 per cent ethanol or 1 *M* sodium chloride without significant loss of titre. However, the addition of 'carrier' ribonucleic acid to a dilute virus preparation also allows some of the infectivity to be carried through ethanol or 1 *M* sodium chloride precipitation; previously, it was found that both ethanol and 1 *M* sodium chloride failed to precipitate virus activity in the absence of carrier ribonucleic acid[5]. The above tests thus show that the material in ribonucleic acid extracts differs considerably from virus, particularly in its heat-lability and susceptibility to ribonuclease, but under our conditions precipitation by ethanol and molar salt cannot be held to show that the material is ribonucleic acid. Moreover, the biological activity of ribonucleic acid extracts differs from that of virus diluted to equivalent infectivity. First, there is the low titre shown by plating ribonucleic acid extracts compared with that shown by injection of the infected cells into mice (Table 1); encephalomyocarditis virus has the same titre both by plating and by mouse titration. Ribonucleic acid extracts and virus, diluted to a comparable level of infectivity, also behave differently when plated on Krebs 2 carcinoma cells which have been treated with ultra-violet light (cell concentration 10^7/ml., lamp 15 watts, 61 cm. distance, 2 min. exposure with agitation). Pre-treatment of cells in this way can increase the apparent titre of a ribonucleic acid extract ten-fold, whereas that of virus is not affected (Table 2).

Simple washing with phosphate-buffered saline of cells which have been treated for 30 min. *in vitro* with ribonucleic acid or virus did not remove virus from the cells, but rendered cell/ribonucleic acid complexes non-infective. Finally, treatment of ribonucleic acid/cell complexes, after 30 min. at room temperature, with either encephalomyocarditis antisera, or inactivated horse serum, destroys the infectivity, a treatment which is without effect upon virus-infected cells.

The amount of infectivity extractable by phenol from infected cells is not directly related to their virus content (Table 1; cf. 'virus' and 'ribonucleic acid' infectivities of 4 and 8 hr. cell samples). This suggested that the infectivity of material extracted with phenol might come from some component other than the virus itself. An infected culture fluid ($5 \cdot 8 \times 10^8$ plaque-forming units/ml.) was therefore centrifuged for 1 hr. at 105,000 *g*, and the supernatant removed and saved. Ribonucleic acid extracts were made from the supernatant, the sediment re-suspended to volume, and the stock from which these materials were prepared. The results are shown in Table 3. Although the virus content of the supernatant fluid was only one-thousandth of that of the sediment, the ribonucleic acid extract of the supernatant had more than ten times the infectivity of that extracted from the sediment. Two other preparations showed that even the residual infectivity of the sediment is probably due to contamination by supernatant material. Virus from a stock containing 2×10^9 plaque-forming units/ml. was concentrated and washed twice by centrifuging at 105,000 *g*; the two preparations contained 3×10^9 and 5×10^9 plaque-forming units/ml., respectively. Phenol extracts showed no infectivity either by plating or by mouse test.

Table 3

Sample	Virus content (plaque-forming units/ml.)	Infectivity of ribonucleic acid extract (MID_{50}/ml.)
Tissue culture fluid	$5 \cdot 8 \times 10^8$	$6 \cdot 3 \times 10^3$
(*a*) Supernatant from 1 hr. centrifuging at 100,000 *g*	$2 \cdot 2 \times 10^5$	$3 \cdot 0 \times 10^3$
(*b*) Sediment from 1 hr. centrifuging at 100,000 *g*	$1 \cdot 2 \times 10^8$	$1 \cdot 6 \times 10^2$
Sediment as in (*b*) washed (1)	5×10^9	0
2 × by centrifuging for 1 hr. at 100,000 *g* (2)	3×10^9	0

The infective material in phenol extracts may thus come from a component in the infected tissue which does not sediment to any extent under conditions which bring down virus. Treatment of infected cell homogenates with ribonuclease removes ultra-violet absorbing material without affecting the infectivity which can afterwards be extracted by phenol[6]. This indicates that the potentially infective material must normally be present intracellularly in a form resistant to the action of ribonuclease.

Ascites tumour cells infected with encephalomyocarditis virus, or the extracellular fluid into which virus has been released by the destruction of infected cells, thus contain, in addition to virus, a second component related in some way to virus synthesis. Phenol treatment breaks this material into fragments carrying the genetic information necessary for the production of virus. The origin and cellular location of this material and the part it plays in virus synthesis is at present wholly obscure. It could be a virus precursor, 'unpacked' viral genetic material incorporated in some cellular structure, or a form of viral ribonucleic acid which has failed to be assembled into complete virus.

When fragments enter competent cells, virus synthesis proceeds. The influence of such factors as ultra-violet light, injection into mice, etc., in inducing cellular competence may be best understood if we consider that virus infection has two distinct aspects. (1) Regarded as the most important until now, the production of new virus, which has been visualized essentially as the replication by the cell of a viral genetic pattern. (2) Since, immediately after virus infection, biosynthesis starts in the cell, we must postulate the existence of some stimulus which triggers the cell to synthesis. We can thus imagine that an infective virus particle carries both the genetic information and the trigger, while the material extracted with phenol carries the specific viral genetical information but lacks the trigger. In this case virus production will only occur when the cell is stimulated to synthesis by other means.

Crystal Structure of Rhombohedral Sulphur

The allotropic form of sulphur first discovered by Engel[1] has been variously termed Engel's sulphur, S_ε, S_ρ, S_φ, trigonal sulphur, and rhombohedral sulphur. The molecule was shown to be hexameric by Aten[2]. Friedel[3] found the crystals were hexagonal prisms terminated by a flat rhombohedron. Although these crystals are largely converted to a mixture of plastic and orthorhombic sulphur an hour or so after they have been exposed to air or X-rays, Frondel and Whitfield[4] were able to determine the hexagonal lattice constants, show that the symmetry axis was three-fold, and demonstrate the absence of vertical planes of symmetry; the lattice constants, combined with the observed density[1], give 18 sulphur atoms per unit cell. The quality of their photographs was such that they were unable to determine whether the lattice mode was hexagonal or rhombohedral. Their X-ray study, however, combined with the morphological observations, established the point group as C_{3i}–$\bar{3}$, and Donnay[5] later pointed out that on purely morphological grounds the lattice is rhombohedral and that the space group is thus probably C_{3i}^2–$R\bar{3}$ (No. 148).

By taking rotation and small oscillation-range Weissenberg photographs around *a* and *c*, each with a different crystal, we have verified directly that the lattice is indeed rhombohedral. For the triply primitive hexagonal cell, we find the provisional values $a = 10{\cdot}83$ A. and $c = 4{\cdot}26$ A., in satisfactory agreement with Frondel and Whitfield's values of 10·9 kX. and 4·26 kX. The general position of C_{3i}^2–$R\bar{3}$ is six-fold; the primitive rhombohedral cell accordingly contains one molecule of S_6.

There are 31 unique (*hk*.0) reflexions accessible to $K\alpha$ copper radiation, and 25 of these have been observed. By the use of intensities estimated with the multiple film technique together with signs for the structure amplitudes obtained with the aid of a map of the molecular structure factor, we have prepared the projection of electron-density on (00.1), Fig. 1. The *x* and *y* parameters measured from this projection must be regarded as preliminary because neither series-termination effects nor errors due to absorption have been taken into account.

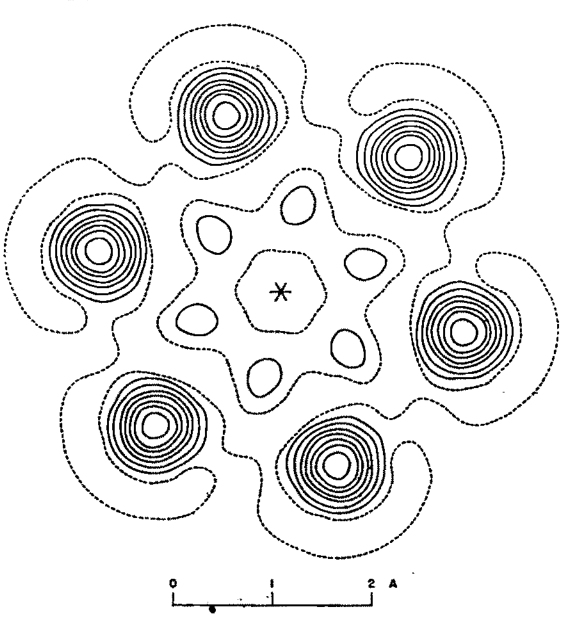

Fig. 1. Electron-density projected down the *c*-axis. Contours drawn at intervals of five electrons per A.^{2} (zero contour dotted)

Our (0*k*.*l*) photographs are somewhat poorer in quality than our (*hk*.0) photographs. Qualitative intensity considerations suggest a value of the *z* parameter of about 1/10. The fact that *z* is not zero means that S_6 molecules are staggered rings with symmetry D_{3d}–$\bar{3}m$. The approximate bond-length is 2·0 A., the bond-angle about 100°. We expect to obtain more precise values for these and other angles and distances of interest when the structure has been more completely refined.

The Four Elastic Constants of Diamond

The thermal scattering of light in diamond has been studied in great detail by R. S. Krishnan[1] and by V. Chandrasekharan[2]. These authors pointed out that the frequency shifts observed for the Brillouin components are not in good agreement with the values calculated using the elastic constants data of Bhagavantam and Bhimasenachar[3]. The values of the elastic constants have since been determined by Prince and Wooster[4] and recently much more accurately by McSkimin and Bond[5]. McSkimin and Bond's values do not agree with those of Bhagavantam and Bhimasenachar and of Prince and Wooster, especially as regards C_{12} and C_{44}. Using the values of McSkimin and Bond, the frequency shifts of the Brillouin components for the various orientations studied by Chandrasekharan with the bigger spectrograph were calculated, but the agreement with the experimental values was still unsatisfactory. We have therefore evaluated the elastic constants of diamond directly from the observed frequency shifts[6].

To achieve this, three values of the frequency shifts must be assumed. For convenience, the shifts of the longitudinal component arising from the elastic waves moving approximately along the direction [$\bar{1}44$], which is inclined at about 10° to [011], and the longitudinal and transverse components of the elastic waves approximately along the direction [811], which is inclined at about 10° to [100], have been taken and, by a perturbation procedure[7], the elastic constants have been calculated. The values are $C'_{11} = 94{\cdot}9$, $C'_{12} = 15{\cdot}1$ and $C'_{44} = 52{\cdot}1 \times 10^{11}$. The accuracy is estimated to be 3–5 per cent, chiefly due to the errors possible in the angle of scattering. Using these elastic constants the effective elastic constants and the Brillouin shifts have been calculated for all the orientations and the results are given in Table 1.

* Values in italics were used in calculating the elastic constants.

Agreement between the experimental and the calculated values of the frequency shifts is very good. It must be mentioned that the exact directions of the hypersonic waves were used in the calculations. It is of interest to see that the observed frequency shifts of the transverse components (cases 2, 6 and 7) are midway between the theoretical values arising from the two transverse waves. Because of their closeness, they were recorded as unresolved.

The values of C'_{12} and C'_{44} obtained by us agree very well with those of McSkimin and Bond, but disagree with the earlier measurements. There seems to be some slight disagreement in C'_{11}.

The values of the elastic constants given by the various workers are collected in Table 2. They fall into two sets, namely, C_{11}, C_{12}, C_{44} and C'_{11}, C'_{12}, C'_{44}.

(1) The values of C_{11} and C'_{11} for all workers agree closely, whereas C_{12} and C'_{12}, C_{44} and C'_{44} disagree very considerably.

(2) The bulk modulus calculated on the basis $\varkappa = (C_{11} + 2C_{12})/3$ agrees well with the observed values, whereas, as already shown by McSkimin and Bond, the value $\varkappa = (C'_{11} + 2C'_{12})/3$ does not agree with the experimental value (column 7 of Table 2).

(3) The values of $(C_{12} + 2C_{44})$ and $(C'_{12} + 2C'_{44})$ are equal (column 6) irrespective of the method of measuring the elastic constants.

These three significant results indicate very clearly that the interpretation of the experiments must be in terms of the atomic theory of elasticity due to Laval[8] and Raman[9], as a consequence of the existence of non-central atomic forces. The elastic behaviour of cubic crystals belonging to T_d, O and O_h classes could be described only by four elastic constants d_{11}, d_{12}, d_{44}, d_{45} and not by the usual three constants of Voigt's formulation. We designate the elastic constants obtained by using Christoffel's equation for the velocity of the linearly polarized plane waves in an infinite medium as the 'wave (dynamic) constants'. From the new theory of elasticity it is known that the values of the compressibility calculated using these constants will not agree with the observed value of the compressibility. Hence, we have identified the dashed quantities (C'_{ij}) in Table 2 as the 'wave (dynamic) constants'. In the pulse-phase comparison and thermal scattering methods the velocities are measured directly and hence the dashed constants are obtained. The undashed quantities (C_{ij}), on the other hand, can be designated as the 'static constants' because they agree with the compressibility data. The values of C_{12} and C_{44} obtained by Bhagavantam and Bhimasenachar fall in the latter (undashed) category. This may be due to the fact that although C_{12} and C_{44} have been calculated individually from the transverse wave equation, the torsional mode may have been excited in their experiments. It is not clear why Prince and Wooster's measurements should give the 'static' values. Probably the theory of diffuse scattering of X-rays needs some modification in the light of the new theory of elasticity.

The new theory demands the two invariants (1) and (3), the former only being pointed out by Viswanathan[10]. Using the following relations, the values of the four elastic constants d_{11}, d_{12}, d_{44}, d_{45} have been calculated.

$$d_{11} = C'_{11} = C_{11}\,;\ d_{44} = C'_{44}\,;$$

$$d_{45} = (2C_{44} - C'_{44})\,;\ d_{12} = (C'_{12} + 2C'_{44} - 2C_{44})$$

The average values of C_{ij} and C'_{ij} have been used to calculate the d_{ij}'s and the numerical values obtained are:

$$d_{11} = 101\cdot9\,;\ d_{12} = 36\cdot6\,;\ d_{44} = 54\cdot9\,;$$
$$d_{45} = 32\cdot1 \times 10^{11}$$

Table 2*

Authors	Method of measurement	C_{11}	C_{12}	C_{44}	$(C_{12} + 2C_{44})$	$(C_{11} + 2C_{12})/3$
Bhagavantam and Bhimasenachar	Wedge method	95	39	43	125	57·7
Prince and Wooster	X-ray diffuse scattering	110	33	44	121	58·7

Theoretical	—	*101·9*	39·9 14·3	41·8 54·5	*123·3*	

* Values in italics were used in calculating the two unknown force constants.

Using these values three further relations have been verified:

$$(1)\ d_{12}\,(36\cdot6) = C_{12}\,(36\cdot0)$$
$$(2)\ (d_{11} + 2d_{12})/3\ (58\cdot4) = \kappa(56)$$
$$(3)\ d_{12} + d_{44} + d_{45}\ (123\cdot6) = C_{12} + 2C_{44}(123\cdot0) = C'_{12} + 2C'_{44}\ (123\cdot3)$$

The existence of the four elastic constants in diamond has thus been definitely established.

We note that in diamond, d_{12} is nearly equal to, but distinctly different from, d_{45}. This is what is to be expected from the (42) equations given by Viswanathan[10]. This difference between d_{12} and d_{45} is due to the lattice-displacement term, which is small even in diamond. In the case of other cubic crystals having all the atoms at the centres of symmetry, such as sodium chloride, this lattice-displacement term is zero and hence $d_{12} = d_{45}$; but d_{44}, in general, will not be equal to d_{45}. In diamond, the difference between d_{44} and d_{45} is large, as is to be expected from the pronounced covalent bonding.

The values of the four elastic constants can be calculated from the atomic force constants. The elastic constants have been evaluated otherwise by Viswanathan[10], but the two sets C'_{ij} and C_{ij} have not been clearly analysed. Taking the average values of $C_{11} = C'_{11}$ $(=101\cdot9)$ and $C_{12} + 2C_{44} = C'_{12} + 2C'_{44}$ $(=123\cdot3)$ and combining these with Ramanathan's[11] evaluation of the force constants from the spectroscopic behaviour of diamond to calculate the two unknown force constants, we get:

$$d_{12} = 39\cdot9\ ;\ d_{44} = 54\cdot5\ ;\ d_{45} = 28\cdot9 \times 10^{11}$$

The values for C_{12}, C_{44}, C'_{12} and C'_{44}, calculated on this basis, are given in the last row of Table 2. The agreement with the observed values is quite satisfactory, and affords further confirmation of our identification.

Accurate measurements of Young's modulus for diamond along the [100] and [111] directions would afford an additional test of the validity of the new theory of elasticity.

Work on other aspects of this problem is continuing and will be published in due course.

Fluorescence of Adsorbed Water

IN previous communications[1] I have discussed what I called 'the reversibility of fluorescence by annealing' which I attributed in the case of chemicals and some pulverized minerals (anhydrite, desmine, colemanite) to adsorbed water, and in the case of the feldspars, which I studied in the form of larger pieces, to contamination by contact with the skin of the hand.

I have now observed the reversible fluorescence due to adsorbed water in feldspars which are sufficiently finely powdered, when the fluorescence destroyed by heating can also be regenerated by wetting or by long exposure to the air. Thus the greenish-blue fluorescence of these minerals can be attributed to adsorbed water which, in their natural state, is probably of magmatic origin. This explains the paradox that feldspars formed from the magma show a fluorescence that can be destroyed by heating; there is no evidence for radio photofluorescence in feldspars which might otherwise have explained this phenomenon.

The fluorescence of adsorbed water, first discovered by Ewles[2], is fairly widely distributed in the mineral kingdom. It is characterized by a broad band in the blue with one or two peaks between 430 and 480 mμ; it can be destroyed by strong annealing and regenerated by weaker heating after a short exposure to damp air, and by longer exposure to the atmosphere at room temperature, as well as by wetting. In many cases the fluorescence in the natural state is also increased by weak annealing.

The bluish colour of the fluorescence is often changed to orange-yellow by annealing, due to the relative enhancement of a long-wave band; it is not clear whether this is due to another activator or to the formation of certain lattice defects. This effect has already been observed in the case of calcite by Kreutz[3] and Déribéré[4], who also noticed the part played by water.

The reversibility of fluorescence by annealing has recently been found in alumina and silica under conditions which exclude any contamination; the only substances with which the powders were in contact, apart from the air of the room, being the interior of Jena glass tubes and platinum cleansed by heating to yellow heat.

Wawilow and Tummermann[5] have observed a bluish fluorescence of water that can be removed only with difficulty by repeated distilling. I have now found that freshly fallen snow and its melt-water, excited by ultra-violet light, display a bluish fluorescence with a peak at 430 mμ, in sufficient agreement with the results of Wawilow and Tummermann. Those authors tentatively ascribe the fluorescence to oxygen, whereas Ivekovic[6] attributes it to organic impurities. It seems possible, however, that this fluorescence, too, may be due to the adsorption of water, not on a solid body but on the molecules of some impurity.

As to the fluorescence of skin[1, 7], which first led to a mistake in the case of the feldspars, the following observations may be added. The aqueous extract of heated skin is brightly fluorescent; on evaporation a brown deposit is formed which is only faintly fluorescent. Rewetting, however, immediately restores the fluorescence.

I wish to thank Dr. H. Adler for his help in these investigations.

Energy Spectrum of Particles Bombarding the Earth

Interstellar matter may be captured by the gravitational field of the Sun. Harrower[1] suggests that this matter is intercepted by the Earth's atmosphere at the 400-km. level, giving rise to radio-star scintillation. He estimates[1] the flux of hydrogen atoms or nuclei of about 10 eV. as of order 10^{13} cm.$^{-2}$ sec.$^{-1}$.

Balmer emissions with Doppler shifts corresponding to proton velocities of order 1,000 km./sec. (energy 10^4 eV.) have been observed in auroral displays. The flux of protons has been estimated[2] as of order 10^7–10^8 cm.$^{-2}$ sec.$^{-1}$. Protons coming from outside the Earth's atmosphere and penetrating to auroral depths must have incident energies of order 10^5 eV. Very little is known about when and where auroral protons reach the Earth.

In the energy region above 10^9 eV., cosmic rays follow an integral energy (E) spectrum given[3] by $N\ (>E) \propto E^{-1 \cdot 5}$. The exponent may increase for $E > 10^{16}$ eV.

The cosmic-ray integral energy spectrum is plotted as a solid line in Fig. 1. The estimated fluxes of interstellar and auroral particles appear to fit the straight-line portion of this spectrum extrapolated to lower energies.

This fit could not be predicted *a priori*, and according to present theories it must be fortuitous or based on inaccurate estimates. Clearly, it is important to examine the intermediate energy intervals.

As shown in Fig. 1, the cosmic-ray spectrum appears to be cut-off at an energy of about 10^8 eV. However, it is known that the flux of particles in this energy region varies greatly with solar activity[4]. It may be supposed, then, that this cut-off is due to some solar influence[3].

The geomagnetic field and the shielding nature of the atmosphere also influence measurements in the energy-range about 10^5–10^8 eV. However, Winckler *et al.*[5] have found a possible association between cosmic radiation and auroral activity. Also Van Allen and others[6] measured the flux of soft radiation at rocket altitudes as much greater at the northern auroral zone than elsewhere.

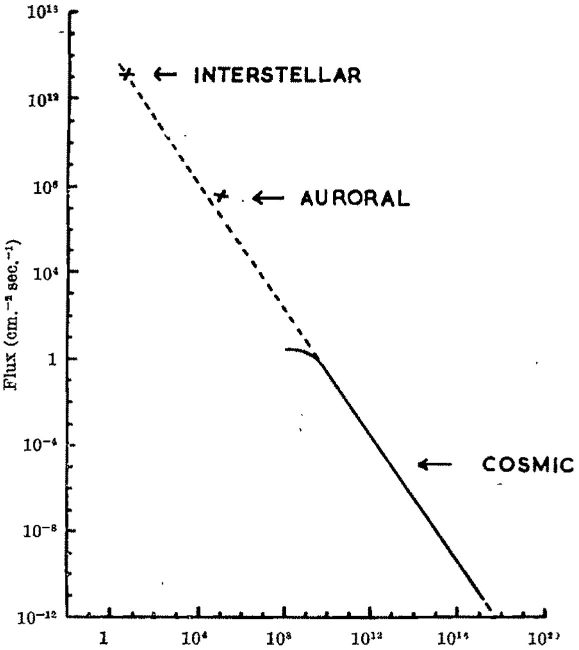

Fig. 1. The integral energy spectrum of particles entering the Earth's atmosphere. The cosmic-ray spectrum is shown as a solid line

Recent measurements using artificial Earth satellites have indicated that the flux of ionizing radiation at an altitude of 1,000 km. is about one thousand times the flux at 100 km. This might be interpreted as further evidence for a continuation of the energy spectrum between 10^6 and 10^8 eV.

The energy-range around 10^5 eV. could be studied by examining height-intensity distributions of auroral Balmer emissions. No accurate measurements are available, and the point plotted in Fig. 1 represents the integral flux estimated by several workers[2]. Chamberlain has found[2] that an integral energy spectrum of $E^{-1/2}$ may govern the auroral protons. However, the uncertainties in this estimate are considerable.

To my knowledge, no quantitative measurements in the energy-range between 10 and 10^5 eV. have been reported.

Since first considering the data presented in Fig. 1, I have seen a recent paper by Parker[7]. He has shown that the cosmic-ray gas can be effectively coupled to motions of ordinary matter, and that this represents a state of general dynamic balance. This treatment suggests that the relation noted in Fig. 1 may not be fortuitous. Clearly, much more theoretical and experimental study of the problem is essential.

Stimulating discussions with members of the Antarctic Division are gratefully acknowledged.

Coherent Scattering of 1·33 MeV. γ-Rays by Lead

The cross-section for coherent (elastic) scattering of γ-rays from a heavy atom is expected to include a contribution from Delbrück scattering, the scattering of light by a static electric field[1]. This contribution should appear as a deviation of the experimental cross-section from the cross-section calculated taking only Rayleigh scattering and nuclear Thomson scattering into account; but uncertainties in both theory and experiment have made it difficult to draw any definite conclusions from the results at low energies[2,3].

We have measured the differential cross-section for elastic scattering of 1·33 MeV. γ-rays from lead using a larger γ-ray source than previous workers[2], and using a different method[4] of examining the scattered γ-ray spectrum. In this method a scintillating crystal is viewed by two photomultipliers 1 and 2, the spectrum of 'gated' pulses from 1 being recorded: thus a pulse from 1 is recorded if it coin-

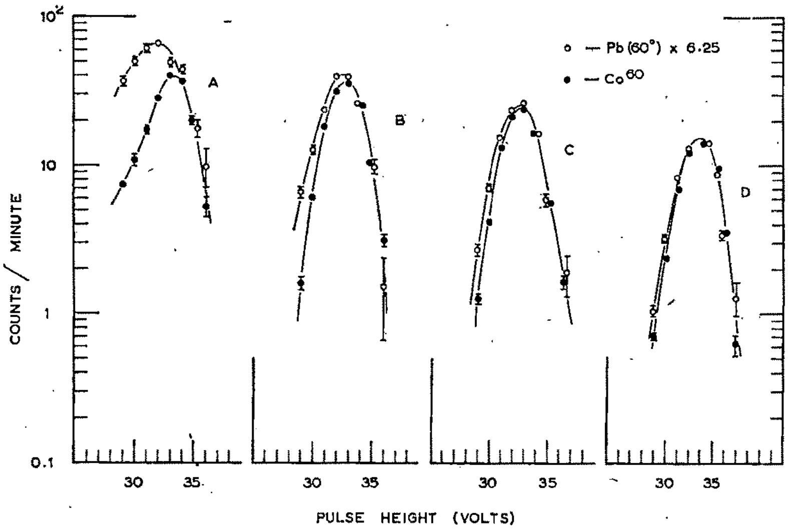

Fig. 1. Gated pulse-height spectra recorded in photomultiplier-1 for various gate voltage settings in photomultiplier-2—the gate voltage increases going from *A* to *D*. ○, γ-Rays scattered from lead at 60°; ●, γ-rays from the small cobalt-60 source *b* at the target position. The counting-rate from the scattered γ-rays has been multiplied by 6·25 in each case

cides with a pulse from 2 greater than a 'gate voltage' *V*. By increasing *V*, the proportion of inelastic scattering included in the measured elastic scattering cross-section may be made negligible.

γ-Rays from a cobalt-60 source *a* (about 1,500 curies) impinged on a lead target (15 cm. × 15 cm.) and the scattered radiation was observed by a NaI(*Tl*) crystal (about 20 cm.^{3}) shielded from background by about 1,200 lb. of lead. The distances source–target and target–crystal were both about 100 cm., so that the angular resolution was between 1 and 2 deg. Measurements under identical conditions were alternated between the scattered radiation (n_a counts/min.) and the direct radiation from a small cobalt-60 source *b* placed at the target position (n_b counts/min.). In each case, light pulses from the crystal were viewed by two photomultipliers[4] as described above. Fig. 1 shows the recorded pulse-height spectra. If no inelastic scattering is being recorded the scattered γ-ray spectrum should have the same shape as the spectrum of the cobalt-60 source. It is clear from Fig. 1 that for low gate voltage considerable inelastic scattering was included—from experiments with thin targets we have found this to be mainly a primary effect (and not a secondary effect of photoelectrons produced by the γ-rays in the target) and to be qualitatively consistent with the Compton scattering expected from bound electrons[5]. As the gate voltage was raised (Fig. 1) the scattered γ-ray spectrum approached that of the cobalt-60 source, giving the ratio n_a/n_b directly. Corrections were made for background ($\lesssim$ 30 per cent) and for target absorption ($\lesssim$ 15 per cent).

At every angle sufficient lead absorber (1–3 in.) was put between the target and the counter to make pile-up negligible. To guard against systematic errors caused by a shift of photomultiplier gain with counting-rate[6], the small cobalt-60 source was accompanied by a cæsium-137 source large enough to give a total photomultiplier current equal to that when the scattered radiation was observed. In addition, we selected as one of our photomultipliers a tube having a gain which increased with increasing counting-rate, and as the other a tube having the opposite characteristics—the change of gain with counting-rate was of the same order of magnitude in the two cases. Measurements taken when first one and then the other of these photomultipliers acted as gating tube, gave upper and lower limits on the ratio n_a/n_b. In all cases, except for the smallest two angles, these agreed within the standard deviations, and for the smallest angles we believe that the combined results are within the standard deviations.

The absolute scattering cross-section is determined by the ratio n_a/n_b, the number of target atoms, the source–target distance, and the ratio *a*/*b* of source strengths. The ratio *a*/*b* was measured in two steps, using an intermediate source *d* of about 150 mc. First the ratio *d*/*b* was measured directly by counting the γ-rays from the sources under identical conditions. Then absorption curves for *a* and *d* (overlapping for a half-thickness) were taken with the same geometry for each. Both curves were exponential and gave an absorption coefficient agreeing with Colgate's value[7], so their ratio was taken for *a*/*d*.

Our experimental cross-sections are shown in Fig. 2. They are lower than those of Bernstein and Mann[2] by factors of 1·3–2·5, and also are much lower than the earlier experimental results[2], but are in fair agreement with the measurements of Goldzahl and Eberhard[2] within the errors of the latter (± 20 per cent).

Fig. 2 also shows the theoretical coherent scattering cross-section. The *K*-shell Rayleigh scattering was

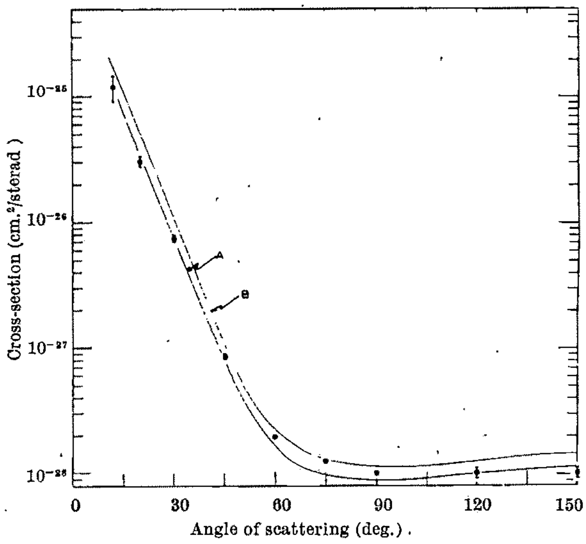

Fig. 2. Coherent scattering cross-section of 1·33 MeV. γ-rays from lead. The points are our experimental points and the bars are standard deviations—where bars are not shown the standard deviations are smaller than the size of the points. In addition to these errors there is an error of ± 5 per cent common to all the points, corresponding to errors in the measurement of the source ratio *a*/*b*. *A*, Theoretical cross-section for nuclear Thomson scattering and Rayleigh scattering from the *K*-shell only; *B*, theoretical cross-section for nuclear Thomson scattering and Rayleigh scattering from the *K*- and *L*-shells

calculated from Brown and Mayers's exact calculations for mercury[3]. These were corrected to lead by multiplying the amplitude for polarization change by the ratio of form factors at each angle, and by multiplying the amplitude for no polarization change by the ratio of Brown and Mayers's 'corrected form factors' at each angle, giving corrections less than, or approximately equal to, 15 per cent in cross-section. The *L*-shell scattering was calculated from the form factor for polarization change and from the 'corrected form factor' for no polarization change.

It is clear from Fig. 2 that if the theoretical results for *K*- and *L*-shells are taken literally, we find an appreciable difference between theory and experiment, amounting, for example, to about 30 per cent at 30°. This difference appears to be qualitatively consistent with present theoretical knowledge of Delbrück scattering[8]. Unfortunately, however, the only accurately calculated Rayleigh cross-section is for scattering from the *K*-shell in mercury[3], and the corrections from mercury to lead and for the contribution of the *L*-shell are of the same order of magnitude as our difference. Furthermore, it appears likely, from the results for the *K*-shell[3], that our *L*-shell calculation is a considerable over-estimate. Therefore, we believe that a final answer as to the presence of Delbrück scattering in our experimental results must await more accurate calculations.

A more detailed report on this work will be published in the *Canadian Journal of Physics*. We are particularly indebted to the Manitoba Cancer Foundation for permission to use its cobalt-60 beam-therapy unit and to the National Research Council of Canada for financial support. We also thank Dr. A. Bernstein, Dr. G. E. Brown and Dr. A. K. Mann for informative discussions and for communication of their results before publication, and Mrs. P. Barnes and Mr. G. Hardie for valuable assistance.

Structure of Precipitated Apatitic Phosphates

TRICALCIUM phosphate (calcium/phosphorus weight ratio, 1·94) is thought to be hydroxylapatite (calcium/phosphorus, 2·15) with phosphate ions chemisorbed. When immersed in lime solutions, this tricalcium phosphate becomes more alkaline and the ratio rises to 2·15. Kinetic studies of lime fixation show that the reaction is not instantaneous. Therefore, it is questionable whether phosphate ions previously in excess should be located on the surface only. On the other hand, the existence of cation defects in the crystalline lattice itself is unlikely.

We think that precipitates of synthetic phosphates must be especially tiny microcrystals, more or less agglomerated, in bigger particles. In such agglomerates, properties connected with structure are not necessarily the same as in perfect macrocrystals. This would account for some properties of the iso-ionic exchange, as well as for other properties of synthetic precipitated phosphates[1].

Catalytic Activity and Surface Structure after Ion Bombardment

SINGLE crystals of silver have been prepared with surfaces having an orientation within 2° of the (111) plane. After bombardment with low-energy argon ions the surfaces have been studied by: (1) measurements of the rate of the catalytic decomposition of formic acid (zero-order reaction); (2) electron diffraction in transmission and reflexion. The results of these experiments suggest that the catalytic decomposition of formic acid on silver occurs at points on the surface where dislocation lines emerge.

Catalysis. The reaction-rate was always expressible as a function of the absolute temperature, T, in the form $A \exp(-E/RT)$. When this was done, both A and E changed with the energy of the bombarding ions. For example, for a maximum ion energy of 14 eV. the value of E was 12·2 kcal./mole; for a maximum ion energy of 77 eV. E became 20·8 kcal./mole and the value of A increased by a factor of $10^{5\cdot2}$. In these experiments the same crystal was used as the catalyst after bombardment with ions of various energies, and the changes in E and A have clearly to be ascribed to a change in the surface due to the bombardment.

We have been able to account for the changes in A only by supposing that there is an increase in the number per unit area of 'active places' on the surface where the reaction can occur. The important feature of these specific sites may be geometric or electronic or both. Assuming that for a given treatment there is mainly one type of site, so that A gives a simple measure of the number of sites, we can say that this number has been increased by the bombardment by a factor of at least $10^{5\cdot2}$. This large increase must be associated with a change in the number of surface defects caused by ion bombardment. Since the crystal is annealed at 250° C. before the measurements are made—and at this temperature defects other than dislocations are reduced to low numbers—this change is most likely to be the result of a change in the number of dislocation lines intersecting the surface.

Electron diffraction. Evidence supporting this last conclusion was obtained from the electron diffraction studies. Bombardment at 14 eV. produced no detectable structure changes in the surface, although silver was removed. Bombardment at 77 eV., however, resulted in the surface layer down to about 100 A. becoming disoriented, small crystalline blocks being rotated with respect to one another mostly through angles of a few degrees. The low angle boundaries between these blocks are commonly described in terms of arrays of dislocations, and the disorientation was found to be comparable to that produced in a crystal of a very heavily cold-worked polycrystalline aggregate in which it is well known that the number of dislocations is about 10^5 times that in an annealed crystal. This implies that the increase in the number of dislocation lines cutting the surface after bombardment at 77 eV. is of the order of 10^5 times the number after bombardment at 14 eV. This increase is similar to that in the number of sites found from the catalytic experiments. We therefore consider that the electron diffraction evidence gives strong support to the conclusion that dislocations cutting the surface provide sites for the reaction.

This work will be fully reported elsewhere.

Tritium and Paper Chromatography

Since hydrogen is an element of fundamental interest in life processes, it is important to have a method for studying its pathway through living systems. If, in paper chromatography, one is using a radioactive tracer, a sheet of X-ray film can be placed on top of the chromatogram and the labelled compounds then produce darkened spots on the film[2]. Unfortunately, in the case of hydrogen, only tritium is radioactive, and this decays by the emission of a very soft β-particle (18 keV.), the range of which is so low that it is absorbed before it can leave the paper and enter the film. This communication describes a technique of 'scintillation autography' whereby this difficulty is overcome. The technique involves soaking the chromatogram in a liquid scintillator so that the energy of the disintegrating tritium atoms is converted into light which is detected by a film. Thus a weak β-particle is converted into light quanta which can travel into the film to produce an image. By the use of fast film, small amounts of compounds labelled with tritium can be separated and identified in only a few days.

This technique is used in our laboratories for researches on the path of hydrogen in photosynthesis. A typical experiment is described to illustrate the technique.

25 mgm. of washed algae (*Chlorella*) are centrifuged to the bottom of a conical centrifuge tube. As much water as possible is removed, since it will lower the specific activity of the tritiated water. 50 mc. tritiated water (4 c./ml.) are added under the particular conditions of the experiment and the whole rapidly agitated with a stream of air with 4 per cent carbon dioxide. At the end of the experiment absolute methanol is added to kill the algae. After extraction with alcohol and water, the extracts are evaporated under vacuum and placed on one corner of a piece of Whatman No. 4 filter paper (15 cm. × 15 cm.) washed in oxalic acid. After development the chromatogram is attached to some suitable backing material with wire staples (used X-ray film is suitable). A spot of extract from algae or yeast labelled with tritium is placed on a piece of filter paper and when dry cut into segments. These segments are then attached to the corners of the backing sheet with staples. These later provide reference points on the backing sheet and also on the film with which to line up the film and the original chromatogram, thus identifying a spot with a definite area on the paper chromatogram. The backing sheet thus prepared is laid in the bottom of a shallow tank and covered with a scintillating liquid (for example, 3 gm./l. *p*-diphenyl benzene in sulphur-free toluene). A sheet of film is next placed on top of the chromatogram, taking care to eliminate any bubbles. The tank is then covered with an air- and light-tight top. After a few days, the film is removed from the tank, drained of scintillating liquid and allowed to dry. It is then developed and fixed in the normal manner. Such a 'scintillation autogram' is shown in Fig. 1. Thus, as in carbon-14 radioautography, compounds can be tentatively identified by their position and this identification confirmed by removal from the paper and co-chromatography with known compounds, or by chemical treatment and re-chromatography.

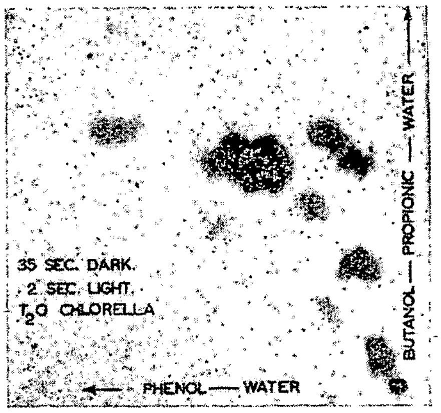

Fig. 1. Example of scintillation autograph

As can be seen, the quality and sharpness compares favourably with radio-autograms produced by beta-particles from carbon-14. Although this technique has been used to study the 'photo' part of photosynthesis in our laboratories, it could also be applied to many other biological and chemical problems. In view of the cheapness and availability of tritium (10^{-4} that of carbon-14), and also the ease of its introduction into complicated organic molecules (by exposure to tritium gas[3]), it should be possible to use it to discover the biological fate of some of the more complex organic materials which are difficult to synthesize with carbon-14. This new technique also provides a method of preparing chromatographically pure tritium-labelled compounds. This overcomes the principal difficulty in the Wilzbach synthesis[3], which yields a product contaminated with small amounts of tritium-labelled material of high specific activity, the removal of which by other means is both tedious and difficult.

A New Method for preparing Scaly Alumina

SCALY alumina is a hydrous alumina with white iridescent scales, similar to white mica sheets. It was first prepared by Neogi and Mitra as the product of the reaction of aluminium amalgam with aqueous barium nitrate solution[1]. The conditions for the formation of scaly alumina were re-investigated by Biltz and Lehrer[2], who found that a saturated barium nitrate solution, at room temperature, gives the highest yield of well-formed sheets of scaly alumina. Neogi and Mitra gave the composition $Al_2O_3.4H_2O$ for the scaly alumina, but this was not confirmed by Weiser[3]. Scaly alumina was considered by Weiser to be a form of Wislicenus's fibrous alumina, but this is not true, since fibrous alumina is formed in conditions different from those in Neogi and Mitra's or Biltz and Lehrer's methods[4].

During studies on the fine structure of scaly alumina by electron microscopy, X-ray diffraction and differential thermal analysis[5], a new method was developed for preparing scaly alumina using hydrogen peroxide instead of the barium nitrate solution. This new method yields a substance identical in appearance to the scaly alumina prepared by the other methods, with the advantage that it is free from the barium and ammonium compounds which are formed in the reduction of the barium nitrate by the aluminium amalgam.

The procedure for preparing the scaly alumina is as follows: a 6 cm. × 6 cm. piece of 99·95 per cent pure aluminium sheet, 0·5 mm. thick and weighing about 5 gm., is washed in a 1-litre beaker, first with acetone, then with *N* sodium hydroxide solution and finally with distilled water to remove the sodium hydroxide; 100 ml. of a saturated mercuric chloride solution are added to the beaker and left to react with the aluminium until the latter is covered with an adherent layer of liquid mercury; the greyish turbid liquid is rejected and the amalgamated aluminium sheet is washed five times with 500 ml. of distilled water to remove the mercury salts; 1 kgm. of twice distilled mercury is added to the beaker, and immediately followed by the addition of cold 3 per cent hydrogen peroxide solution. The amalgamated aluminium sheet floats on the surface of the mercury, covering it almost completely and starts reacting with the hydrogen peroxide solution, with a strong production of gas and heat. The beaker is placed in a refrigerator at 4–5° C. to slow down the reaction; after 24 hr. the surface of the mercury is covered with a thick layer of white iridescent sheets of scaly alumina.

The scaly alumina may be separated from the hydrogen peroxide solution and from the mercury by filtration in a Buchner funnel without filter paper, and washed with distilled water. It must be dried at room temperature, in air or in a vacuum desiccator to preserve its iridescent scaly appearance, which is lost when it is dried at more than 70° C. The amount of scaly alumina obtained by this procedure corresponds to a yield of 40–45 per cent from the original weight of the aluminium sheet. The amalgamated aluminium sheet, floating on the surface of the mercury, gives better sheets of scaly alumina than does the aluminium amalgam, prepared from aluminium powder[6], in Biltz and Lehrer's method[2]. If the reaction is allowed to proceed until all the hydrogen peroxide in the solution is used up or if the temperature becomes too high, no scaly alumina is formed, but a dark grey powder appears, as in the reaction of strongly amalgamated aluminium with water[7].

Table 1

Substance	Loss on ignition (per cent)
Scaly alumina, Biltz and Lehrer's method (ref. 2)	31·4
Scaly alumina, H_2O_4 method	38·3
$Al_2O_3.3H_2O$ (theoretical)	34·7
$Al_2O_3.4H_2O$ (theoretical)	41·4

Table 1 shows the results of the determinations of the loss of weight on ignition at 1,200° C. of samples of scaly alumina prepared by Biltz and Lehrer's methods and by the procedure described above. These results are for samples dried at 110° C. to constant weight. For comparative purposes, the theoretical ignition losses of an alumina trihydrate and a tetrahydrate are also presented in the table.

These results show that the scaly alumina prepared by Biltz and Lehrer's method is closer in composition to an alumina trihydrate than to a tetrahydrate. The lower ignition loss is probably due to barium impurities adsorbed between the layers of the scaly alumina. The scaly alumina prepared by my method is closer in composition to an alumina tetrahydrate; however, no alumina tetrahydrate exists[8], only the mono- and tri-hydrates. Therefore, the scaly alumina prepared using hydrogen peroxide solution must be an alumina trihydrate with some water adsorbed between the layers. These results are confirmed by the X-ray powder diffraction data of the samples prepared by both methods[5]. A detailed study on the structure of the scaly alumina will be published elsewhere.

α-(*p*-Nitrophenyl)Maltoside as a Substrate for the Assay of Amylase

RECENT methods for the assay of amylase use polysaccharides, mostly starch solutions, as a substrate. The wide range of the results can be ascribed in part to the properties of polysaccharides in solution. In starches the ratio of amylose to amylopectin is variable and, according to Meyer, long-chain polysaccharides in solution tend to form particles resistant to enzyme. The affinity of amylase for the substrate diminishes with decreasing chain-length. The maltose set free acts as an inhibitor of amylase (cf. Meyer *et al.*). Moreover, the moderate accuracy of the usual (iodometric and reductometric) methods of measuring chain-length may affect the results unfavourably.

An improved method for the assay of amylase seemed possible, using maltotriose as a substrate.

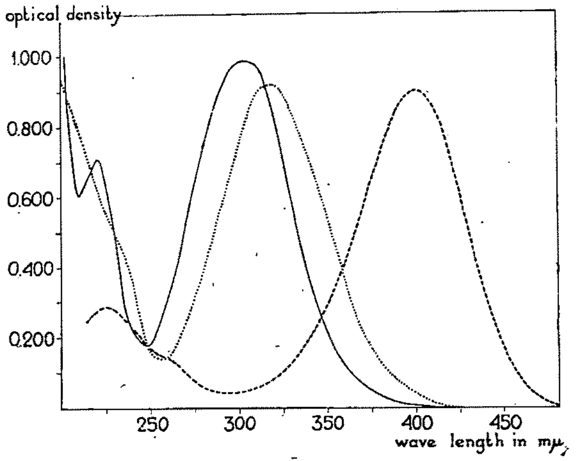

Fig. 1. Absorption spectra of α-(*p*-nitrophenyl)maltoside in acid and alkaline solution (solid line) and of *p*-nitrophenol in acid (dotted line) and alkaline solution (interrupted line). 'Unicam' spectrophotometer 500, 10-mm. cuvettes, intervals of 5 mμ.

However, unanimity does not exist about the action of amylases on maltotriose. According to Meyer *et al.*[1] and Pazur *et al.*[2], maltotriose is broken down to glucose and maltose at a very slow rate, whereas Wheelan *et al.*[4] and Myrbäck *et al.*[5] deny that maltotriose is degraded by salivary amylase.

We have studied the breakdown of maltotriose photometrically, using α-(*p*-nitrophenyl)maltoside as a substrate. The strong yellow colour of *p*-nitrophenol, set free during hydrolysis, makes it possible to measure a slight degradation and to avoid high concentrations of maltose.

Synthesis of α-(*p*-nitrophenyl)maltoside was performed by the following procedure, analogous to the synthesis of 4-methyl-α-(*p*-nitrophenyl)glucoside by Berger[6]:

$$\text{Maltose} + \text{acetic anhydride} \rightarrow \text{octa-acetylmaltose}$$

$$\text{Octa-acetylmaltose} + p\text{-nitrophenol} \xrightarrow{\text{TiCl}_4} (p\text{-nitrophenyl})\text{hepta-acetylmaltoside}$$

$$(p\text{-Nitrophenyl})\text{hepta-acetylmaltoside} + \text{methanol} \xrightarrow{\text{sodium methylate}} \text{methylacetate} + p\text{-nitrophenyl maltoside}$$

Titanic chloride catalyses formation of the α-form of glycosidic linkage[6]. Absorption spectra of the amorphous substance in alkaline and acid solution were identical, indicating linkage of the phenolic OH-group of *p*-nitrophenol to maltose (Fig. 1). *p*-Nitrophenol was set free while boiling with alkali.

Hydrolysis of the substrate was obtained during incubation with saliva, urine, duodenal contents and incidentally with serum.

Table 1. Influence of High Temperature (boiling 15 min.) and Protein Precipitants on Hydrolysis of α-(*p*-nitrophenyl)maltoside by Human Urine and Saliva, expressed as Optical Density at $\lambda = 410$ mμ

	Untreated	Boiled	10 per cent trichloracetic acid		0·5 *N* silver nitrate
			0·1 ml.	0·2 ml.	0·1 ml.
Urine	0·190	0·020	0·090	0	0
Saliva	0·320	0	0·130	—	0

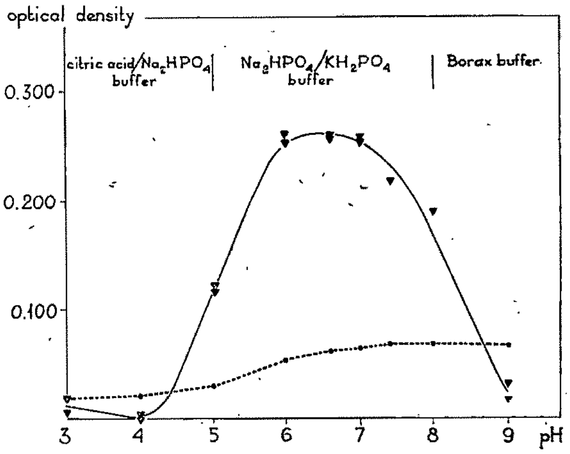

Fig. 2. Relationship between *p*H and hydrolysis of α-(*p*-nitrophenyl)maltoside by human urine, expressed as optical density at $\lambda = 410$ mμ. The dotted line represents the hydrolysis of the blanks, measured against water

2 mgm. of substrate, dissolved in 3 ml. of 1/15 *M* phosphate buffer (*p*H 6·5) were incubated with 0·1 ml. of the material to be tested at 37° C. for 16 hr. Then 10 ml. of 0·02 *N* sodium hydroxide were added. Production of *p*-nitrophenol was measured photometrically at 410 mμ. For each determination a blank was prepared by adding the material to be tested to the incubated substrate after it had been made alkaline. If necessary, enzyme solutions were diluted so as to produce optical densities less than unity.

The rate of hydrolysis is dependent on the *p*H (Fig. 2) with an optimum at *p*H 5·9–7·0. High temperature and protein precipitants inhibit hydrolysis (Table 1). These results suggest an enzymatic activity. The relationship of hydrolysis to enzyme concentration is linear; *p*-nitrophenol does not inhibit the reaction.

Apart from the possible existence of an unidentified carbohydrase[4,7], our results suggest that human amylase is able to degrade maltotriose to glucose and maltose, so that α-(*p*-nitrophenyl)maltoside may be a suitable substrate for the assay of amylase.

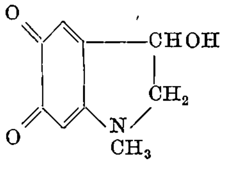
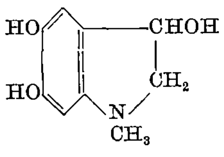
Reduction of Adrenochrome with Ascorbic Acid

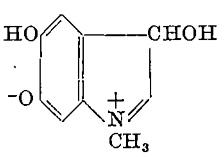
The discharge of the intense red colour of aqueous solutions of adrenochrome (I) by various reducing agents has been reported by several workers[1,2]. The reaction apparently does not simply consist of the reduction of the orthoquinone moiety of the molecule with the production of the hypothetical 'leuco-adrenochrome' (2 : 3-dihydro-3 : 5 : 6-trihydroxy-N-methylindole) (II). Harley-Mason, in describing the reduction with sodium hydrosulphite or hydrogen (catalytic), postulated the initial addition of one atom of hydrogen to the molecule, with the formation of an unstable intermediate which disproportionates into (II) and a zwitterionic compound (III). The former (II) appears to be inherently unstable and readily loses water, with the formation of 5 : 6-dihydroxy-N-methylindole (IV); the second substance (III) isomerizes under the influence of alkali to adrenolutin (3 : 5 : 6-trihydroxy-N-methylindole) (V)[2,3].



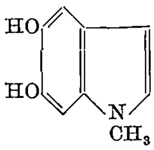
(I)



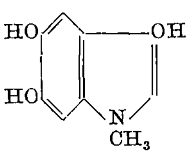
(II)



(III)



(IV)



(V)

The reduction of adrenochrome with ascorbic acid, a reaction which may have physiological significance, has been reported by Beauvillain and Sarradin[4] and by Fischer[5], who reported that this reduction product is not the same as that produced by sodium bisulphite. However, the isolation of definite reduction products was not described in either case.

We have studied the ascorbic acid-reduction products of adrenochrome, both in aqueous and methanolic solution, by paper chromatography, and the results indicate the presence of three or possibly four compounds giving chromogenic reactions characteristic of indole derivatives. All these substances also exhibited fairly marked reducing properties. The excess ascorbic acid and resulting dehydroascorbic acid were also easily detected.

Spots consisting of 10–60 μlitres of the reaction mixture (prepared from adrenochrome (0·05 gm.) and ascorbic acid (0·25 gm.) in 10 ml. solvent) were examined on Whatman No. 1 paper (previously washed with 2 per cent acetic acid) in three solvent systems: (*A*) 2 per cent acetic acid in water; (*B*) *n*-butanol/acetic acid/water (6 : 1 : 2) and (*C*) acetonitrile/acetone/water/acetic acid (80 : 5 : 15 : 1).

The chromogenic reagents employed were: (1) Ehrlich's reagent; (2) cinnamaldehyde; (3) Hopkins-Cole reagent[6]; (4) Salkowski reagent; (5) Gibbs phenol reagent; (6) diazotized *p*-nitroaniline; (7) ammoniacal silver nitrate; (8) ferric chloride-potassium ferricyanide[7]; (9) dichlorophenol-indophenol and (10) 2 : 4-dinitrophenylhydrazine.

The results obtained are given in Table 1.

In *A*, the R_F zone 0·42 ± 0·01 exhibited the characteristic colour reactions of indoles and *o*-catechols and was due to (IV). (An authentic sample of (IV) prepared from (V)[3] had the same R_F.) The zone R_F 0·83 ± 0·03 was due to dehydroascorbic acid and unchanged ascorbic acid. (Authentic specimens of these acids had R_F's of 0·86 and 0·85 respectively in this solvent; ascorbic acid gave a black spot, whereas dehydroascorbic acid gave a golden-brown spot with ammoniacal silver nitrate.) The unknown substances (VI) and (VII) with R_F values of 0·56 ± 0·02 and 0·65 ± 0·05 respectively showed modified indole reactions together with phenolic and reducing properties. In *B* (IV) had an R_F of 0·76 ± 0·02, (VI) had an R_F of 0·27 ± 0·01 and once again ascorbic acid and dehydroascorbic acid were not efficiently separated and were present in the zone R_F 0·39 ± 0·02. (Authentic samples had R_F's of 0·36 and 0·42 respectively.) In *C* (IV) had an R_F of 0·96, (VI) had an R_F of 0·55 ± 0·02 and the two acids were observed at an R_F of 0·37 ± 0·02.

Table 1. R_F VALUES OF MAJOR REACTION PRODUCTS IN VARIOUS SOLVENT SYSTEMS (see text)

*A**	*B*	*C*
0·42 ± 0·01 0·56 ± 0·02 0·65 ± 0·05 0·83 ± 0·03	0·27 ± 0·01 0·39 ± 0·02 0·76 ± 0·02	0·37 ± 0·02 0·55 ± 0·02 0·96

* In some cases, a weak spot was observed at R_F = 0·04.

In order to obtain more information about the nature of the compounds present in the reaction mixture, the individual R_F zones were eluted from the paper (larger quantities were applied in streaks to Whatman No. 3 *MM* paper and development effected with solvent *A*) and the ultra-violet spectra determined in ethanolic solution. All three zones gave similar absorption curves typical of the indole chromophore. (Zone R_F 0·42 ± 0·01: $\lambda_{\max.}$, 281; 301: $\lambda_{\min.}$, 252; 288. Zone R_F 0·56 ± 0·02: $\lambda_{\max.}$, 283; 301: $\lambda_{\min.}$, 255; 289. Zone R_F 0·65 ± 0·05: $\lambda_{\max.}$, 275; 282: $\lambda_{\min.}$, 260; 279 with shoulder at about 300 mμ.) The curve obtained from the zone R_F 0·42 ± 0·01 was identical with that of an authentic specimen of (IV).

Paper chromatographic examination of the products derived from adrenochrome by reduction with ascorbic acid, in aqueous solutions, after extraction with peroxide-free ether, indicated that the substance with R_F 0·42 ± 0·01 was removed by the ether, while all the other products remained in the aqueous phase. Crystalline 5 : 6-dihydroxy-N-methylindole (melting point 134–135° C.; melting point of diacetyl derivative 109·5–110·5° C.) was isolated from the ethereal extract.

Other reducing agents for adrenochrome not previously reported include dihydroxymaleic acid, dihydroxyfumaric acid, cysteine, and sodium borohydride (in this case, crystalline IV has been isolated from products). These studies are being continued and further details will be published elsewhere. This investigation forms part of a programme being carried out under the auspices of the Saskatchewan Committee on Schizophrenia Research and was supported by grants from the Saskatchewan Government, the Federal Department of Health and Welfare and the Rockefeller Foundation.

Photosynthesis of Amino-Acids

It has been observed in this laboratory that when aqueous mixtures of dicarboxylic or monocarboxylic acids and certain ammonium salts are irradiated with ultra-violet light, certain amino-acids are obtained.

A cold quartz ultra-violet lamp giving 86 per cent of its output at about 2537 A. was used for irradiated mixtures of succinic, maleic, propionic and acetic acid with a number of ammonium salts. These mixtures were 0·1 molar both in organic acid and ammonium salt. The irradiation was continued in each case for 24 hr., the area of the irradiated solutions being 44 cm.^{2}, and the radiation intensity 7,500 microwatts/cm.^{2} at the surface of the liquid.

Of all the ammonium compounds investigated only ammonia and ammonium carbonate were active, and of the acids only succinic, maleic and propionic acid gave rise to amino-acids.

An absorption curve in the ultra-violet region, with a peak at 2750 A., was obtained for succinic acid irradiated in presence of ammonia or ammonium carbonate. This indicates the presence of a C=O group, which was confirmed by positive tests for aliphatic aldehyde; tests for ketone were negative. Aldehydes were not detected after irradiation of maleic and propionic acids.

The irradiated solutions were evaporated to dryness, the residue taken up with acidified acetone (in 1 per cent hydrochloric acid) for desalting, the acetone was evaporated and the residue dissolved in a few drops of *iso*propylic alcohol (10 per cent in water).

Paper chromatograms were made from these *iso*propylic solutions, using phenol saturated with water as solvent for ascending chromatography in the presence of sodium cyanide and standard solutions of amino-acids for comparison.

Table 1 gives the amino-acids detected after irradiation of organic acid – ammonium salt mixtures.

Table 1. AMINO-ACIDS DETECTED AFTER 24 HR. EXPOSURE TO ULTRA-VIOLET, λ = 2537 A.

Mixture	Amounts of amino-acids found		
	Aspartic acid	Alanine	Glycine
Succinic acid and ammonia		++	+++
Succinic acid and ammonium carbonate		++	+++
Succinic acid and ammonium thiocyanate		+	
Maleic acid and ammonium carbonate	+++	++	+
Propionic acid and ammonium carbonate			+++

Key: +++ very large, ++ large and + trace.

It must be concluded that ultra-violet, at a wavelength of 2537 A., is able to synthesize amino-acids from mixtures containing either a saturated dicarboxylic acid such as succinic acid, an unsaturated dicarboxylic acid such as maleic acid or a monocarboxylic acid such as propionic acid with carbonate or thiocyanate and ammonia.

The amino-acids are aspartic acid, alanine and glycine, that is to say, amino-acids with 4, 3 and 2 carbon atoms respectively.

Only succinic acid gives an aliphatic aldehyde after irradiation.

A browning reaction occurs during the evaporation of the irradiated solutions, the intensity of which is dependent on the nature of the organic acid.

A full description of the results obtained in this field will be published later.

A Colorimetric Test for Gibberellic Acid and Evidence from a Dwarf Pea Assay for the Occurrence of a Gibberellin-like Substance in Wheat Seedlings

A RECENT communication by McComb and Carr[1], reporting the use of a dwarf pea bioassay for naturally occurring gibberellins, prompts this report of some results of an experiment designed to investigate whether gibberellic acid occurs naturally in etiolated wheat seedlings.

Wheat (var. Eclipse) was grown in darkness for four days at 25° C. on moist filter paper contained in 11-cm. Petri dishes. In all, 12,500 coleoptiles with enclosed primary leaves were excised at 96 hr.; these were cut transversely into halves, representing the basal region, including the leaf meristem (135 gm. fresh weight), and the tip (205 gm. fresh weight). Basal and tip sections were frozen separately to − 15° C. in 2·5 l. of phosphate/citrate buffer of *p*H 3·8 and, after thawing, the tissue was filtered. Peroxide-free ether (3·3 l.) was passed over the tissue and shaken with the filtrate in five aliquots. The resulting ether fraction was extracted with 4·4 l. of 1 per cent sodium bicarbonate in five aliquots. This solution was then acidified to *p*H 3·0 with sulphuric acid and extracted five times with a total of 3·3 l. of peroxide-free ether.

Each of the two acidic and neutral fractions was reduced to small volume and transferred, as a series of spots on the starting line, to 25·5 cm. square Whatman No. 1 chromatography papers. Four sheets were used for each fraction. The chromatograms were developed by ascending chromatography, using the solvent system *iso*propanol/ammonia (0·880)/water (10 : 1 : 1), the papers being removed when the solvent front had moved 23 cm. Each sheet was cut horizontally into nine strips each 2·5 cm. wide; these strips were then eluted with acetone, which in each case was concentrated to 2·5 ml. The thirty-six eluates were each transferred to 25·5 cm. square Whatman No. 1 chromatography papers as a single spot for development in two directions in the solvent systems, (*a*) *iso*propanol/ammonia (0·880)/water (10 : 1 : 1); (*b*) *n*-butanol/ammonia (0·880)/water (200 : 6 : 36). In each case the solvent was allowed to move 23 cm. Papers were dried between development in a current of air. Finally the papers were sprayed with Folin and Ciocalteau's[2] reagent and kept in darkness for 4 hr. at 25° C. I find that this reagent gives a characteristic colour with gibberellic acid.

When gibberellic acid, melting point 232–233·5° C. (decomposition), supplied by Imperial Chemical Industries, Ltd., was resolved in each of the above solvent systems and the chromatograms sprayed with this reagent two bright blue spots appeared as follows: (1) a dense blue spot, R_F value 0·52 in system (*a*) and 0·24 in system (*b*); the material extracted from this position on the unsprayed paper was found to induce a growth response in dwarf pea plants as described below. (2) a small blue spot, R_F value of 0·04 in system (*a*) and 0·00 in system (*b*); this material from the unsprayed paper was found not to induce a growth response in the dwarf pea test. The lower limit of detection on a two-way chromatogram using this colorimetric test is about 5 μgm.

None of the chromatograms from the tissue extracts described here showed a positive colour response with the reagent. In order to detect the possible presence of gibberellic acid in quantities less than 5 μgm., a bioassay was carried out using dwarf pea seedlings. Dwarf peas (var. Meteor) were planted in moist sand, four in each 14-cm. pot, and grown for seven days under glasshouse conditions. Pots showing uniform growth were selected for treatment. When one drop of a solution of gibberellic acid (1–5 μgm.) in 10 per cent aqueous acetone was applied to the growing tips of such plants a considerable stimulation to growth was observed. This increase over control growth could be readily assessed. The acetone eluates from the different segments of the chromatograms obtained from the plant extracts, each representing a specific zone on the paper, were examined in this test. One drop (about 0·05 ml.) of the acetone solution added to 0·5 ml. of water was applied to the tips of four plants. Measurements of the total height of the plants were taken ten days after the treatment. Results for the acidic fractions are summarized in Fig. 1.

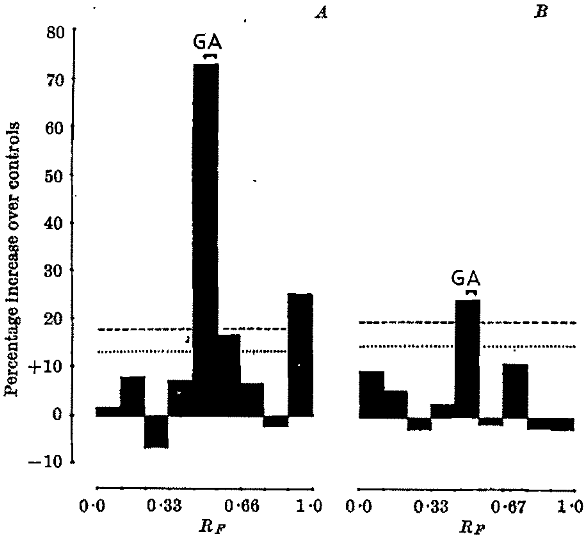

Fig. 1. Bioassay of extracts from wheat seedlings. The growth of dwarf Meteor peas is expressed as percentage increment over control. The increment for control plants treated with 1 μgm. per plant of gibberellic acid (G.A.) is 470. *A*, Extract from basal portion of wheat seedling shoots; *B*, extract from tips of wheat seedling shoots. Significant difference from control: – – –, (P = 0·01); . . . ., (P = 0·05)

It will be noted that a highly significant activity was found in the extract obtained from the basal region of wheat seedlings and that some activity was found in the extract from the tips of seedling shoots. Furthermore, the activity observed from the wheat extracts is seen to be associated with the gibberellic acid area of the chromatogram. In addition, there is an area of activity at, or near, the solvent front in the extract from the basal portion of the wheat seedling shoot.

Since the growth response corresponding to the region R_F 0·44–0·56 of the wheat seedling chromatograms was very considerably less than that obtained with 1 μgm. of gibberellic acid, it is not surprising these chromatograms gave a negative test with the Folin and Ciocalteau's reagent. The results presented here, however, provide evidence that gibberellin-like materials occur naturally within the tissues of wheat seedlings.

Advice and assistance from Prof. R. L. Wain are gratefully acknowledged.

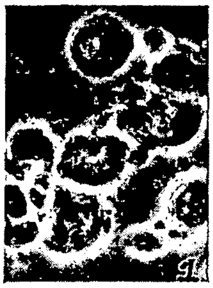
Possible Use of Synthetic Surface-active Agents for the Preparation of Tumour Cell Nuclei

WHILE the observation has been made that surface-active agents will produce lysis of the plasma membrane of cells[1, 2], little use seems to have been made of this observation for the preparation of nuclei[3]. Some preliminary observations suggest that nuclei may be prepared in large numbers from a variety of cells, without the use of special apparatus, by treatment with the anionic surface-active agent, sodium lauryl sulphate. Nuclei prepared in this manner are at least as free from cytoplasm as those prepared by the method of Hogeboom *et al.*[4]. In the case of some tumours, such as the *V*–2 carcinoma of the rabbit, they are very much cleaner (Figs. 1 and 2).

Suspensions of tumour cells have been prepared from frozen and fresh tumour by light grinding in a porcelain mortar in 5 volumes of 0·15 *M* saline. The suspensions were filtered successively through No. 80 gauze and 80- and 120-mesh wire screens. The tumour cell suspensions were stirred on ice and 0·4 per cent sodium lauryl sulphate, at room temperature, in 0·15 *M* saline (*p*H 6·9) added. Small drops were removed periodically for observation by phase-contrast microscopy. At concentrations of the surface-active agent of approximately 15 to 20 × 10^{-4} *M* most of the nuclei were free from cytoplasm. Small wisps may adhere to some nuclei when certain tumours are treated. When an optimum freeing of nuclei has been observed, these may be recovered by centrifugation and washing in 0·15 *M* saline. Similar results may be obtained by substituting 0·25 *M* sucrose for the 0·15 *M* sodium chloride.



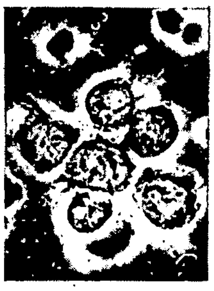


Fig. 1. Fragmented cells of *V*–2 rabbit carcinoma after treatment in glass tube homogenizer with 'Teflon' pestle; method of Hogeboom *et al.* (ref. 4). (× 500)

Fig. 2. Crude preparation of nuclei of *V*–2 carcinoma cells. Prepared in saline and sodium lauryl sulphate. (× 500)

Lysis of cells of *V*–2 carcinoma of the rabbit seems to proceed in several steps: swelling of cytoplasm, rupture of the cell membrane, fragmentation of the cytoplasm, freeing of the nuclei, and finally extraction of the nuclear nucleoprotein. This latter step occurs at a concentration of approximately 31×10^{-4} *M* (ref. 5), and results in nuclear ghosts. The nuclei so prepared meet the criteria of Philpot and Stanier[6], namely, intact membranes without blebs, no clumping, intact nucleoli, normal granularity, and extractability of highly polymerized deoxyribonucleic acid. It is realized that morphological criteria may not be sufficient indications of the functional integrity of the nuclei. Biological experiments attempting to elucidate this point are under way. So far most work has been with the *V*–2 carcinoma, but nuclei have also been prepared from the Ehrlich ascites tumour, spontaneous mammary carcinoma of the mouse, and mouse lymphoma.

Experiments with the cationic detergent cetyl trimethylammonium bromide and the non-ionics 'Tween 80' and 'Triton *X*-102' have resulted in cytolysis but have not caused freeing of the nuclei. The non-ionic 'Triton *X*–45' and anionics sodium 2,4- and 2,5-dimethylbenzene sulphonate have occasionally caused the appearance of free nuclei, but not in sufficient number for preparative purposes. Experiments are in progress utilizing other anionic detergents containing the sulphate group and with non-ionic and cationic agents containing a lauryl side-chain.

This work has been supported in part by grants from the American Cancer Society and the National Cancer Institute of the U.S. Public Health Service (*CY*–3475).

Effect of the Borate Ion in Buffers on the Electrophoresis of Rat Serum

It has recently been reported that the electrophoretic mobility of certain protein components of human[1,2], bovine and rat[3] sera are altered in buffers containing borate. A more extensive investigation of the effect of borate buffers has been carried out in this laboratory during the past two years, during work on the transport of vitamin A alcohol in rat serum (Garbers, C. F., Gillman, H., and Peisach, M., unpublished work). These results are briefly recorded here.

A borate–phosphate buffer, *p*H 8·6 and $I = 0{\cdot}05$, was used for the preparative electrophoretic separation of rat serum proteins on partially acetylated cellulose powder columns[4,5]. A protein component migrating faster than the albumin during electrophoresis was observed (Fig. 1). Fractions 6–18, forming the albumin peak were analysed in the analytical ultracentrifuge ('Spinco' Model *E*). The albumin peak consisted of at least three components, namely, albumin, macroglobulin and the third component which migrated faster than the albumin on electrophoresis. This component possessed the sedimentation properties of a globulin (Fig. 2), stained positive for a glycoprotein[6] and, on paper electrophoresis in the veronal buffer had a mobility slightly lower than the albumin. When the non-complexing veronal buffer, *p*H 8·6 and $I = 0{\cdot}05$, was used for the preparative electrophoretic separation, this glycoprotein component did not migrate in front of the albumin, although the position of the macroglobulin was unaltered.

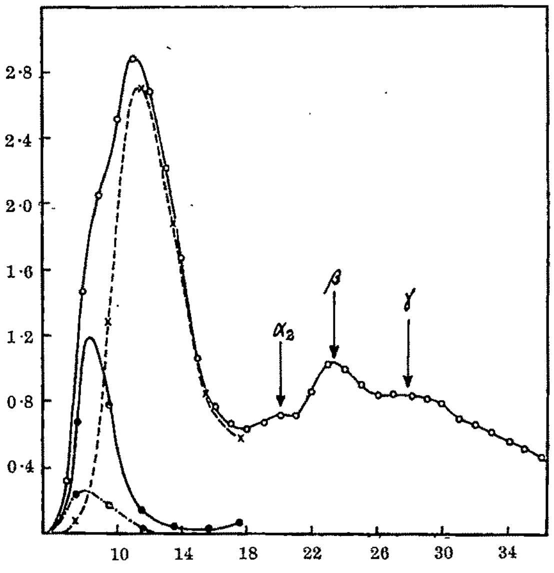

Fig. 1. Eluate from electrophoretic separation on a cellulose powder column (2 × 32 cm.) of rat serum proteins (3 ml.) using the borate–phosphate buffer, *p*H 8·6, *I* 0·05. —O—O—, total protein; —×—×—, albumin; —●—●—, α_1-glycoprotein; –.–●–.–●–.–, macroglobulin

Investigation of this phenomenon by paper electrophoretic techniques established that, in the rat, most of the mucopolysaccharides are associated with the α_1-globulin. In the complexing borate buffer this α_1-glycoprotein component acquires a mobility which

is greater than that of the albumin, whereas in the non-complexing veronal buffer its mobility is less than that of the albumin (Fig. 3).

Formation of Activated Amino-Acids by Intact Cells of *Azotobacter vinelandii*

It has been shown[1-4] that various preparations of enzymes which activate amino-acids convert them into a form which is adsorbed on charcoal, is unstable to alkali, and which reacts with hydroxylamine to form amino-acid hydroxamates. These 'activated' amino-acids seem to be amino-acid-polynucleotide compounds[1-4], and have been suggested[4] as intermediates in protein synthesis, because the amino-acid of such compounds is incorporated into the protein of isolated microsomes. Activated amino-acids have been formed only in cell-free preparations, and it is of considerable interest to determine whether similar compounds are formed by intact cells.

Cells of *Azotobacter vinelandii* were suspended in 0·1 *M tris*-(hydroxymethyl)-aminomethane buffer (*p*H 7·25) containing 0·5 μc. of glycine or leucine labelled with carbon-14. After varying periods of time, the temperature of the suspension was reduced to 1° C., and the cells were broken by sonic vibration. Cellular debris was removed by centrifuging at 30,000*g*. Protein was precipitated from the supernatant solution with 6 per cent perchloric acid and isolated as described previously[5]. 1 gm. of charcoal was stirred into each 10 ml. of the perchloric acid extract. The charcoal was collected by centrifugation, washed twice with 0·05 *M* potassium phosphate, and twice with 0·1 *M* potassium acetate. Control experiments demonstrated that this washing removes all free glycine or free leucine from the charcoal. The charcoal, however, contains considerable amounts of bound glycine or leucine. If the charcoal is extracted with 0·2 *M* hydroxylamine, the glycine or leucine is removed as glycine- or leucine-hydroxamate. These substances migrate on paper chromatography along with authentic samples of the respective hydroxamates. The amino-acids, therefore, are apparently bound by their carboxyl groups to some substance which is adsorbed by charcoal. At 25° C., the 'amino-acid-*X*' is stable for at least 6 hr. at *p*H 7, but is degraded, with the liberation of free glycine, at higher *p*H values. For example, it has a half-life of about 60 min. at *p*H 8, and of 20 min. at *p*H 9. The amino-acids are not bound as an artefact due to sonic vibration, as cells disrupted by an osmotic technique[6] also contain glycine adsorbable on charcoal.

Table 1. Incorporation of Glycine labelled with Carbon-14 into Protein and Glycine-*X* of *Azotobacter vinelandii*

Time (sec.)	Counts per min. per mgm.	
	Glycine-*X*	Protein
0	0	0
5	205	0
15	278	0
30	305	9
120	318	28
300	413	117
900	505	311
3,600	486	3,300
900 (plus 6×10^{-4} *M* chloramphenicol)	710	180
900 (plus 10^{-3} *M* cobalt ions)	550	215

Table 1 presents the time course of incorporation of glycine labelled with carbon-14 into protein and into the charcoal-adsorbable fraction of *Azotobacter* cells. Detectable amounts of labelled glycine cannot be found in protein until at least 30 sec. after the cells have been placed in the labelled glycine solution. In contrast, the fraction adsorbable on charcoal has incorporated considerable amounts of glycine within 5 sec. Table 1 also shows that both chloramphenicol and cobalt ions, which are inhibitors of protein synthesis, enhance slightly the incorporation of glycine into 'glycine-*X*'.

The various properties of this material resemble the properties of the activated amino-acids reported by other investigators, and suggest that intact cells incorporate amino-acids into some activated form which is at least similar to that obtained in cell-free preparations. The activated glycine obtained from *Azotobacter* cells does, however, differ from other preparations in that it is not precipitated by ethanol from a phenol extract by the method of Kirby[7]. It may be that the amino-acids are not bound to polynucleotide in intact cells, or they may be bound to a rather small polynucleotide. Determination of the exact nature of these amino-acid compounds and their relationship, if any, to cellular protein synthesis requires further investigation.

Formation of Phosphoserine from 3-Phosphoglycerate in Higher Plants

STUDIES with carbon-14 dioxide in plants have indicated that serine may be formed from glycine[1,2], and previous results from this laboratory[3] have shown that serine and glycine are interconvertible in plant tissues. However, other studies[4,5] have indicated that serine may be formed before glycine, and this communication presents evidence that serine may be formed *via* phosphoserine from phosphoglycerate, a pathway previously demonstrated in animals[6].

D-3-Phosphoglycerate-^{32}P was prepared by a modification of the method of Neuberg and Lustig[7]. The purity of the compound was established by chromatography and the chromatographically pure compound was eluted from the paper. The enzyme system was prepared from 8–10 day old pea epicotyls (110 gm.) grown in the dark, by grinding with sand and phosphate buffer (0·2 *M*, *p*H 7·4, 200 ml.). The homogenate produced was strained through linen and centrifuged until it was clear. Solid ammonium sulphate was added to 80 per cent saturation, and the suspension was centrifuged at 30,000*g* for 10 min. The precipitate was dissolved in 10 ml. of the above buffer and dialysed against 2 l. of 0·05 *M* phosphate buffer (*p*H 7·4). All operations were carried out at 2°.

The enzyme (1·0 ml.) was incubated with D-3-phosphoglycerate-^{32}P (5 μmoles), diphosphopyridine nucleotide (3 mgm.), L-glutamate (25 μmoles), pyridoxal phosphate (0·05 μmole), and phosphate buffer (1·0 ml., 0·2 *M*, *p*H 7·4), in a total volume of 2·5 ml. for 2 hr. at 37° C. The reaction was stopped by addition of absolute ethanol to a final concentration of 50 per cent, and the precipitated protein was spun down and discarded. A control experiment in which the reaction was stopped at zero time was included.

Table 1. SYNTHESIS OF PHOSPHOSERINE-^{32}P FROM PHOSPHOGLYCERATE-^{32}P

Experiment	Phosphoglycerate-^{32}P	Phosphoserine-^{32}P	Unidentified (*C*) (phosphoserine-^{32}P)
Zero time (c.p.m.)	10,900	0	0
2 hours (c.p.m.)	8,400	670	190
2 hours (percentage initial phosphoglycerate-^{32}P)	77	6	1·7

Incubation as in text. Radioactivity measurements corrected for decay.

1·5 ml. of the resulting solutions were applied as streaks to paper chromatograms which were run in ethyl ether, formic acid (60 : 40) at 2°. Autoradiographs of these chromatograms showed that a compound with the same R_F as phosphoserine was formed after incubation but was absent at zero time. This compound was eluted, carrier phosphoserine added, and placed as a spot on a paper chromatogram which was run in phenol saturated with water–formic acid (96 : 4). Phosphoserine was detected by spraying with ninhydrin, and the radioactivity found to coincide with this area (*A*, Fig. 1). Marker spots of phosphoserine were placed on the paper and similarly sprayed with ninhydrin. The action of ninhydrin on phosphoserine produces phosphoglycolaldehyde. The paper was then run in the other direction with *t*-butanol, water, picric acid (80 : 20 : 2 v/v/w). An autoradiograph showed the presence of two radioactive compounds. The compound with the lower R_F (*B*, Fig. 1) had the same R_F (0·5) as the marker phosphoglycolaldehyde, formed from carrier phosphoserine and was found to coincide exactly with the radioactive area. The faster running radioactive compound (*C*, Fig. 1) has not been identified, but

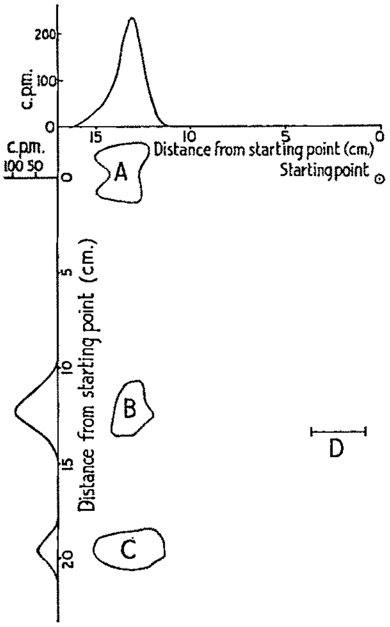

Fig. 1. Identification of phosphoserine-^{32}P formed from D-3-phosphoglycerate-^{32}P. *A*, Phosphoserine-^{32}P; *B*, phosphoglycolaldehyde-^{32}P; *C*, unidentified; *D*, R_F of phosphoglycolaldehyde. Chromatogram run in: horizontal, phenol saturated with water–formic acid (96 : 4); vertical, *t*-butanol, water, picric acid (80 : 20 : 2 v/v/w).

may be an isomer of phosphoglycolaldehyde[8]. The quantitative yield of phosphoserine is shown in Table 1.

The individual reactions involved in the synthesis of phosphoserine :

$$\text{D-3-Phosphoglycerate} + \text{DPN}^{+} \rightleftharpoons \text{phosphohydroxypyruvate} + \text{DPNH} + \text{H}^{+}$$

$$\text{Phosphohydroxypyruvate} + \text{L-glutamate} \rightleftharpoons \text{phosphoserine} + \alpha\text{-oxo-glutarate}$$

have been demonstrated, and the specificity and properties of the enzymes are under investigation.

We are indebted to the Royal Society and the Agricultural Research Council for grants towards apparatus and chemicals, and to the Agricultural Research Council for a maintenance grant for one of us (J. H.).

Effect of Copper on Growth and Catalase Levels of *Corcyra cephalonica* St. in Zinc Toxicity

THE work of Smith and Larson[1], van Reen[2] and van Reen and Pearson[3] has revealed that the dietary ingestion of toxic levels of zinc results in a marked inhibition of growth and deranged iron metabolism in rats. The latter effect was reflected in anæmia and decreased levels of liver catalase and cytochrome oxidase. Liver extract partially counteracted the growth inhibition, while minute supplements of copper to the toxic diet reversed the anæmic condition[1] and restored the levels of the iron enzymes[2]. From such results it has been concluded that the inhibition of growth is unrelated to the enzymic changes observed, and that the two phenomena are distinct and different effects of zinc toxicity in the animal organism.

In view of our earlier studies on zinc toxicity in the larvæ of the rice moth, *Corcyra cephalonica* St.[4], it was thought of interest to investigate the zinc–copper relationship from this point of view. For this purpose, groups of 10–15 day-old larvæ, weighing between 7·0 and 9·0 mgm. per ten, were grown for a period of three weeks on the following diets : (1) control, basic diet of sieved wheat flour ; (2) zinc toxic-basal diet plus 0·4 per cent $ZnSO_4,7H_2O$; (3) zinc toxic diet as in (2) with graded amounts of $CuSO_4,5H_2O$; and (4) zinc toxic diet supplemented with 1·0 per cent liver extract. The last group, namely, that with liver extract, was included for purposes of comparison with earlier work[1–4]. The experimental procedure involved in the preparation of the liver extract and the rearing of the larvæ has been described in detail elsewhere[4]. Growth was recorded at weekly intervals. At the end of three weeks, larvæ from each group were weighed and homogenized in $M/15$ phosphate buffer (pH 7·0). Catalase activity was determined by allowing aliquots of the buffer extract to act upon 0·05 M hydrogen peroxide and titrating the unreacted hydrogen peroxide, at the end of the reaction period, with $N/100$ potassium permanganate, according to the procedure of Ramachandran and Sarma[5]. Catalase activity was expressed as ml. of $N/100$ permanganate consumed per gm. of larval tissue per minute. The results obtained in a typical experiment are shown in Table 1.

Table 1. INFLUENCE OF COPPER ON ZINC TOXICITY IN RICE MOTH LARVÆ

No.	Supplements to basal diet (10 gm. sieved wheat flour)*	Weight of 10 larvæ (mgm.)				Catalase units
		At transfer	1st week	2nd week	3rd week	
1	Control (no zinc)	7·7	38	105	226	493·2
2	None	8·3	22	57	100	309·1
3	0·005 per cent copper sulphate	7·0	23	56	103	393·6
4	0·01 per cent copper sulphate	8·2	22	59	98	540·6
5	1·0 per cent liver extract	6·0	31	94	194	315·5

* Unless otherwise stated, all diets also contained 0·4 per cent zinc sulphate.

It can be seen that the intake of toxic amounts of zinc brings about not only an inhibition of growth but also a pronounced fall in tissue catalase activity. 0·01 per cent copper sulphate, added to the zinc-toxic diet, restores the enzyme levels without, however, improving growth to any extent. Sivarama Sastry, Radhakrishnamurty and Sarma[4] have recently shown that this growth inhibition can be considerably reversed by the inclusion of liver extract in the toxic diet. The results presented in Table 1 show that liver extract has little effect on catalase activity, however.

These results indicate that the inhibition of growth and in catalase activity are separate effects of zinc toxicity in the insect organism, as in the rat[1,2], and point to the probable multiplicity of metabolic disturbances involved in zinc toxicosis. Since it is well known that catalase level in animal tissues is decreased by either an iron or copper deficiency[6] and that copper influences iron metabolism[7], it is likely that the antagonistic behaviour of zinc and copper brought out by the present investigation is a reflexion of an adverse effect of zinc on iron metabolism in the larvæ. It is also possible that such an interference with iron metabolism is a common phenomenon in zinc toxicosis.

Effect of Nicotinic Acid on the Cholesterol Contents of Rat-Livers

LOWERING of the blood cholesterol level by means of large doses of nicotinic acid has been described by Altschul[1], and this effect has been confirmed by others[2]. This effect is caused by nicotinic acid only and its mechanism has not yet been clarified. The use of the amide of the nicotinic acid is said to be without effect.

Table 1

Percentage nicotinic acid in diet	No. of rats	Liver content: Total cholesterol (mgm. per cent)	P	Total lipids (per cent fresh weight)
0	8	1,181·5		25·0
1	10	1,038·3	$< 0·5$	30·8
2	10	923·3	$< 0·2$	31·0
3	10	683·7	$< 0·01$	24·4
4	10	634·1	$< 0·01$	25·2
Normal diet (*C*)	10	220·0		5·0

50 Sprague–Dawley rats (male), ranging in weight from 110 to 120 gm., were fed for 21 days on a special hypolipotropic diet free from cholesterol. This caused an endogenous fatty liver of the cholesterol type (group *A*) (unpublished work). Another group received the same diet but with nicotinic acid in increasing amounts, namely, 1, 2, 3 and 4 per cent (group *B*). A third group (*C*) was fed a normal diet. All animals were killed at the end of this experiment under light ether anæsthesia; after exsanguination the livers were processed according to Sperry's method, and total lipid[3] and cholesterol contents were determined. The results are given in Table 1. Increased cholesterol contents were found in the livers of the animals fed the special diet, the content in group *A* (without nicotinic acid) being six times as great as that in group *C* (normal diet). Liver cholesterol decreased with increasing nicotinic acid in the special diet, but 4 per cent nicotinic acid did not reduce the cholesterol level to its normal value. Nicotinic acid, *per se*, tends to produce fatty degeneration of the liver[4] and intolerably large doses may be necessary to bring the liver cholesterol produced by the special diet to its normal level.

This antilipotropic effect of nicotinic acid can be interpreted as due to the demand of its detoxication products for methyl groups. Detoxication may occur via nicotinic acid, which needs coenzyme A for synthesis. It is suggested, therefore, that this effect is caused by infiltrative fattening of the liver and reduced synthesis of cholesterol (relative lack of coenzyme A).

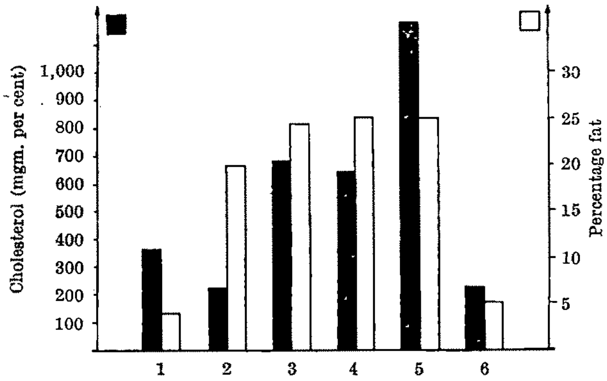

Fig. 1. Cholesterol and fat contents of rat livers after feeding the special diet with (1) 2 per cent α-phenylbutyric acid, (2) 2 per cent α-diphenylylbutyric acid, (3) 3 per cent nicotinic acid, (4) 4 per cent nicotinic acid, (5) control group *A*, (6) normal diet, group *C*

Altschul[1] explained the lowering of the level of cholesterol in the blood by nicotinic acid as due to increased oxidative catabolism of cholesterol. Merill[5], working with rabbits, has suggested possible detoxication products of nicotinic acid, but his work has not afforded clear proof of the inhibition of acetylation *in vivo*. Recent investigations *in vitro* have demonstrated inhibition of acetylation[6], but such experiments *in vitro* cannot establish the influence of nicotinic acid on synthesis of cholesterol.

Comparison investigations using α-phenylbutyric acid and α-diphenylylbutyric acid has led to the following suggestions (Fig. 1): (1) that synthesis of cholesterol is decreased by the influence of nicotinic acid, and (2) that a relative lack of coenzyme A is the causative mechanism.

Effect of Splenectomy on the Phagocytic Activity of the Reticulo-Endothelial System

THE reticulo-endothelial system comprises groups of cells situated in various parts of the body having the ability to take up particulate and colloidal matter. The cells of this system, which have an intimate relationship with the circulation, are to be found mainly in the liver and spleen, from which organs about 95 per cent of intravenously injected particulate material may be recovered[1] and of this amount we have found in mice that the spleen contains less than 5 per cent.

It is generally recognized that the macrophages of the splenic sinusoids play an important part in various physiological and pathological processes. It has been shown by Nicol *et al.*[2] that prolonged œstrogenic stimulation appeared not only to produce a greater formation and activation of reticulo-endothelial cells in the spleen but also assisted their mobilization and liberation into the circulation. This might, therefore, suggest that the importance of the spleen in phagocytic activity is not adequately reflected by the small amount of injected particulate or colloidal matter which is to be found in that organ. The present investigations were planned to ascertain the effect of splenectomy on the rate of removal of particulate matter from the circulating blood.

The following experiments were carried out on 70 male white mice (*T.O.* Swiss strain) of 20–25 gm. body-weight. The phagocytic activity was measured by the rate of disappearance of a known amount of carbon from the circulating blood, as described in a recent communication[3]. The total body phagocytic activity or phagocytic index is denoted as previously by the symbol *K*.

Twenty-five of the animals were used as controls. They were given carbon only and showed an average phagocytic index or *K* value of 26 ± 4·8. The remainder of the animals were divided into two groups and treated as follows. Group I: Twenty-seven mice were splenectomized, the spleen being removed through a left subcostal incision under open-ether anæsthesia. The incision was closed in two layers using fine silk. The animals made an uneventful recovery and appeared to be little affected by the operative procedure. Group II: Eighteen animals were subjected to a left subcostal incision, the spleen being examined but not removed and the wound being closed as in Group I.

In both groups the phagocytic index was then assessed for batches of three animals at varying times from 6 hr. to 8 days after the operation. The results are shown in Table 1. It can be seen that, in the splenectomized animals, 6 hr. after the operation there is marked depression of phagocytic activity, the phagocytic index being reduced to $K = 8$, and that recovery to within normal limits occurs in about 4 days. In the animals subjected to a similar operation in which the spleen was not removed (mock splenectomy) the phagocytic activity also becomes depressed after 6 hr. but to a lesser extent than in the splenectomized animals, and recovery to normal limits takes about 7 days.

Table 1. EFFECT OF SPLENECTOMY AND 'MOCK SPLENECTOMY' ON THE PHAGOCYTIC ACTIVITY OF THE RETICULO-ENDOTHELIAL SYSTEM

Time following operation	Phagocytic index (*K* value)	
	Group I Splenectomized animals	Group II 'Mock splenectomized' animals
6 hr.	8	13
1 day	10	10
2 days	13	
3 days	12	12
4 days	20	12
5 days	23	
6 days	25	16
7 days	29	23
8 days	22	

Phagocytic index for 25 control animals not undergoing operation, 26 ± 4·8.

The results show that after splenectomy there is marked depression of phagocytic activity for about 4 days and this appears to be chiefly the effect of the anæsthetic and operative procedure. The speedier recovery of phagocytic activity in the splenectomized animals to within normal limits is probably due to the compensatory action of the liver, but experiments of several months duration may be necessary to confirm this.

Infectivity of Ribonucleic Acid from Mice and Tissue Culture infected with the Virus of Foot-and-Mouth Disease

SEVERAL workers[1-5] have recently reported the preparation of infective ribonucleic acid from tissues or tissue cultures infected with animal viruses, using the phenol method described by Gierer and Schramm[6] for tobacco mosaic virus. In this laboratory, ribonucleic acid prepared by the same method from pig kidney tissue cultures infected with the virus of foot-and-mouth disease (strain 997—Waldmann type *C*) has been shown (*a*) to induce cytopathic effects in pig kidney cell monolayer cultures, (*b*) to paralyse and ultimately kill unweaned mice if administered intramuscularly, and (*c*) to yield in tissue culture and in mice virus of the same immunological type as the original strain (complement fixation and serum neutralization tests).

Although direct evidence is still lacking, the following observations are regarded as pointing to the absence of residual virus from the preparations. Treatment of the preparations either with ribonuclease (at a concentration of 10 μgm./ml.) or with normal guinea pig serum abolishes their infectivity for mice and for tissue cultures, whereas the virus is unaffected by these treatments. None of the ribonucleic acid preparations so far examined has been infective when inoculated intraperitoneally into mice although the virus is highly infective when inoculated by this route. Skinner, at this Institute, has shown that intramuscular inoculation of virus into unweaned mice gives an end point higher than that obtained by intraperitoneal inoculation. For strain 997 we have found in three experiments that this difference is about 0·4–0·7 log unit, comparable with that found by Skinner for some other strains. This difference would at first suggest that the infectivity of the ribonucleic acid (inoculated intramuscularly) might be due to residual virus which would not be detected by the intraperitoneal route, since in general the ribonucleic acid prepared from pig kidney tissue culture fluids with a virus titre of $10^{4\cdot5}$ *ID*50 0·03 ml. (intraperitoneal inoculation of unweaned mice) had a 50 per cent end point dilution of $10^{-0\cdot5}$ (intramuscular inoculation). That this is not so is indicated by the following experiments. A concentrate of pig kidney tissue culture fluid prepared by precipitation with ammonium sulphate which contained $10^{6\cdot0}$ *ID*50 0·03 ml. (intraperitoneal inoculation of unweaned mice) and $10^{8\cdot3}$ *ID*50 ml. (titration in pig kidney cell monolayers) gave a ribonucleic acid preparation which was non-infective intraperitoneally but killed mice at a dilution of 1/10 inoculated intramuscularly and infected pig kidney cell monolayer cultures at a dilution of 1/100. In another typical experiment 0·3 ml. of the ribonucleic acid failed to infect any of 10 mice inoculated intraperitoneally whereas 0·03 ml. of the same preparation killed all of 10 mice inoculated by the intramuscular route.

Infection of the kidney cells and the mice with ribonucleic acid led to the production of apparently complete virus. This virus was neutralized by type specific guinea pig antiserum but not by normal serum.

Some experiments have also been done with a neurotropic strain of the virus[7,8]. This virus, which is type *A* (complement fixation test), regularly infects adult mice when inoculated intracerebrally. The ribonucleic acid prepared from the brains of such infected mice was infective for mice by the intracerebral route. If the ribonucleic acid preparation was first treated with ribonuclease it was non-infective. The harvested brains from the animals infected with the ribonucleic acid preparation were fully infective for mice by intracerebral inoculation and fixed complement with type *A* guinea pig antiserum.

We wish to thank Mr. H. H. Skinner for carrying out some of the experiments with the neurotropic strain and Dr. F. K. Sanders for discussions and many helpful suggestions.

Change in Oxygen Consumption of the New-Born Pig with a Fall in Environmental Temperature

THE oxygen consumption of the new-born pig during the first day of life increases[1] to the extent of approximately 1 ml. oxygen/kgm.min. per 1° C. fall in environmental temperature over the range 38–20° C. The mean level of oxygen consumption rises between the first and second days, and the inverse relation between metabolism and temperature is maintained[2]. It is therefore of interest that Holub, Forman and Ježková have reported[3] the absence of an increase in the metabolism of pigs from three to six days of age when the environmental temperature is lowered from 23° to 3° C. Observations have now been made on an experimental pattern similar to that adopted by those authors on pigs from birth to six days of age. The results obtained fail to confirm those of Holub *et al.*; indeed, there was a marked rise in oxygen consumption in every case when the temperature of the surroundings fell from near 23° C. to approximately 3° C.

18 Large White pigs, of both sexes and taken from six litters, were used in these experiments; six were less than 1 day old, including two which had not been suckled by the sow (weight range: 1·07–1·40 kgm.), six were 2–4 days old (weight range: 1·15–1·72 kgm.) and six were 5–6 days old (weight range: 1·56–2·72 kgm.). They were born in a farrowing house (general air temperature: 7–15° C.) fitted with creeps heated by infra-red lamps. Consumption of oxygen at both environmental temperatures was measured by spirometer, in a closed circuit system with continuous removal of carbon dioxide. The consumption was measured for individual pigs first in the region of 23° C., then at 3° C., then again at 23° C. Measurement periods were never less than 30 min., and were always preceded by an equilibration period of 10–15 min. in either chamber. Omission of an adequate equilibration period gave spuriously low figures for the consumption of oxygen, due to the unreliability of readings of air temperature taken within the first few minutes after the closing of the chamber. Rectal temperatures were recorded four times for each pig, that is, before each measurement period and at the end of the experiment.

Table 1. OXYGEN CONSUMPTION OF NEW-BORN PIGS IN THE FIRST WEEK OF LIFE AT ENVIRONMENTAL TEMPERATURES OF APPROXIMATELY 23° AND 3° C. SIX PIGS IN EACH AGE GROUP

Age	Environmental temperature (°C.) Mean ± S.E.	Oxygen consumption (ml. dry gas at S.T.P./kgm. min.) Mean ± S.E.
Under 1 day	22·8 ± 0·4 3·1 ± 0·1 22·2 ± 0·1	21·6 ± 1·1 34·5 ± 1·1 24·9 ± 1·0
2–4 days	23·3 ± 0·9 3·8 ± 0·9 23·0 ± 0·2	25·7 ± 0·9 38·8 ± 0·9 26·0 ± 0·6
5–6 days	24·1 ± 0·6 5·0 ± 0·5 23·6 ± 0·5	22·7 ± 0·6 35·9 ± 1·2 22·9 ± 1·0

In every case the consumption of oxygen was considerably greater at 3° than at 23° C.; contrary to the findings of Holub *et al.*, in no case did the consumption fall or remain at the same level with exposure to the lower temperature. The results for three groups of pigs are given in Table 1. The average figures for oxygen used were 23·3, 36·4 and 24·6 ml./kgm.min. for the three succeeding periods at average temperatures of 23·4°, 3·9° and 22·9° C., respectively, and the differences between consumptions at the two temperatures are highly significant for all three age-groups.

The rectal temperature changes are given in Table 2. The fall was most marked in the youngest group at 3° C., but even here considerable recovery took place during the third measurement period, at 23° C. At 5–6 days of age, rectal temperature did not change during the period at 3° C.

Table 2. INITIAL RECTAL TEMPERATURES OF NEW-BORN PIGS AND CHANGES OCCURRING DURING EACH PERIOD OF MEASUREMENT. SIX PIGS IN EACH AGE GROUP

Age	Initial rectal temperature (°C.) Mean ± S.E.	Rectal temperature changes during 1st period (°C.) Mean ± S.E.	2nd period (°C.) Mean ± S.E.	3rd period (°C.) Mean ± S.E.
Under 1 day	38·6 ± 0·1	−0·4 ± 0·1	−1·7 ± 0·3	0·9 ± 0·2
2–4 days	39·1 ± 0·2	−0·3 ± 0·02	−0·6 ± 0·2	0·2 ± 0·2
5–6 days	39·5 ± 0·3	−0·4 ± 0·1	0 ± 0·1	−0·2 ± 0·1

Thus these results show a vigorous response from the new-born pig to lowering of the environmental temperature, in contrast with the absence of response found by Holub *et al.* under similar conditions, and using the same breed of pig. Moreover, this response occurred with pigs, down to 1 hr. of age, which had not been suckled previously by the sow, whereas the youngest animals used by Holub *et al.* were 3 days old. The type of response in respect of oxygen consumption reported here for new-born pigs was not found by Holub *et al.* in pigs younger than 9–10 days of age, and the same is approximately true for rectal temperature changes; the changes in rectal temperature for pigs up to 4 days old (Table 1) correspond generally with those found by Holub *et al.* in pigs aged 10–20 days.

The possibility arises, therefore, that these contrasting results are due to pigs differing constitutionally in their response to lowered environmental temperature. However, before such an outstanding variation among pigs could be accepted, it would be necessary to establish equality of experimental conditions between the two series of experiments.

It is concluded that under the conditions described here the new-born pig responds to a drop in environmental temperature from 23° to 3° C. by a rise in the production of heat of the order of 50 per cent.

Ringed Appearance of Lipid Spheres under the Phase-Contrast Microscope

Recently, Chou and Bradbury[1] have pointed out some optical artefacts produced in the appearance of fat droplets under the phase-contrast microscope. They say that homogeneous fat droplets may have a "crescentic" appearance if examined in a non-axial light source or an eccentric condenser. They also point out that in a fully centred system the appearance of such a fat globule is a "perfectly symmetrical sphere with a dark rim or apparent 'cortex' surrounding the bright region within".

A great variety of living cells have been examined in this laboratory[2] under phase-contrast and interference microscopes and it has been often observed that a non-axial phase-contrast system gives the typical "crescentic" appearance to the lipid spheres that occur so commonly in the animal oocytes, gland cells, and neurones. Such an artefact, however, can easily be detected since it invariably causes a great loss in overall contrast, as is quite evident from the photomicrograph *B* in Fig. 1 of Chou and Bradbury[1].

The ringed appearance of fat or lipid droplets in a perfectly adjusted phase-contrast system has, however, led many cytologists to misinterpret the structure of these homogeneous lipid spheres as duplex.

Similarly, students of oogenesis have very commonly described the so-called Golgi bodies (lipid spheres) as duplex vesicles with a dark cortex and a clear medulla, after using such apparently harmless techniques as fresh coverslip preparations treated with osmium tetroxide solution for short periods[2]. These workers were further misled by the exactly similar appearance of these Golgi bodies under the phase-contrast microscope, in the living material, especially in the animal oocytes. Some extensive work in this laboratory on the histochemistry of oocytes has conclusively shown that these Golgi bodies are nothing but homogeneous lipid spheres colouring uniformly with sudan black *B* in ordinary circumstances. The duplex appearance of the lipid spheres of some oocytes in sudan black *B* has no correlation with their duplex appearance either in osmium tetroxide solution or in the living cells examined under the phase-contrast microscope, because, in such cases, the duplex appearance in sudan black *B* is due to the presence of either solid or masked lipids[3]. This appearance can easily be changed by using special techniques. That the duplex appearances of the homogeneous lipid bodies under the phase-contrast microscope are optical artefacts becomes amply clear from the observations on earthworm oocytes and human oral epithelium, described below.

The oocytes of *Pheretima posthuma* have numerous lipid spheres in the cytoplasm besides the mitochondria and some clear vacuoles. There is no yolk. The lipid spheres colour homogeneously, without any clear medulla whatsoever, in sudan black *B* used on gelatin sections of material fixed with formaldehyde-calcium (Fig. 1*a*). In the living oocytes examined under the phase-contrast microscope the larger spheres appear as clear and sharp rings (Fig. 1*b*).

The loose human oral epithelial cells have a number of homogeneous sudanophil lipid spheres of various sizes. The larger ones always have a ringed appearance under the phase-contrast microscope (Fig. 1*c*).

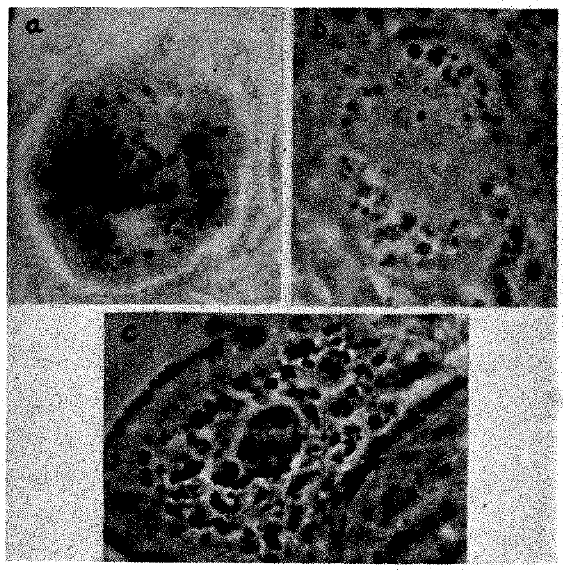

Fig. 1

Some similar observations were also made by Roque[4] on the neurones of the gastropod, *Helix*. These observations clearly show that the duplex or ringed appearance of the lipid spheres under the phase-contrast microscope is an optical artefact.

It may be mentioned that the duplex ringed or crescentic appearance given by the Golgi bodies in the male germ cells (for example, in pulmonate gastropods[4,5]) and certain gland cells (for example, liver cells of *Anadenus*[6,7]) under the phase-contrast microscope are not to be considered artefacts as they have a non-lipid core.

Great care should therefore be taken in interpreting the appearance under the phase-contrast microscope of cell inclusions in general and lipid spheres in particular; these may always be checked carefully using some vigorous lipid colourant like sudan black *B*, as was also pointed out by Baker[8].

Carl Zeiss (West Germany) stand *W* and Leitz 'Dialux' microscopes with phase-contrast systems were used in this work. Living cells were mounted in Baker's[9] physiological solution.

Counting of Sulphate-reducing Bacteria in Mixed Bacterial Populations

In the dilution method of counting *Desulphovibrio* in soil or water, a selective medium containing lactate and inorganic salts is commonly employed. The growth of a sulphate reducer is recognized by the appearance of the black colour of ferrous sulphide. Since the organisms are anaerobes and the medium is simple in composition the addition of a reducing agent is essential. Grossman and Postgate[1] selected cysteine as the most suitable of the reducing substances they examined. Cysteine possesses the disadvantage that it may be attacked with the liberation of sulphide by certain bacteria which do not reduce sulphate. Hence it is necessary to apply some test to confirm the presence of *Desulphovibrio* in cultures which become black. A further disadvantage in the method proposed by Grossman and Postgate is that the cultures are incubated in an anaerobic atmosphere.

Much interest has been taken in the corrosive action on iron for which *Desulphovibrio* is notorious. In contrast, little attention has been given, except by Starkey and Wight[2], to the favourable influence of elemental iron on the growth of the organism. It has been recognized for a long time that metallic iron will lower the oxidation-reduction potential of media to a level suitable for *Clostridia*, and that these anaerobes will multiply readily in tubes of liquid media incubated in air if a strip or rod of iron is included in the medium. This suggested that for the purpose of dilution counts of *Desulphovibrio*, iron, which would not affect the selectivity of a synthetic medium, might be used to provide the necessary reducing conditions. Iron was therefore tested in a medium used by Starkey[3]: sodium lactate, 3·5 gm.; NH_4Cl, 1 gm., K_2HPO_4, 0·5 gm.; $MgSO_4.7H_2O$, 2 gm.; Na_2SO_4, 0·5 gm.; $CaCl_2$, 0·1 gm.; Mohr's salt, trace; and tap water to 1,000 ml.; *p*H 7. The medium was sterilized in quantities of 5–7 ml. in 5/8-in. tubes. Iron was added as a nail 3–5 cm. long and 0·3–0·4 cm. thick, either before or after the tubes of medium were sterilized. Other supplements were sterilized in the medium. All media were used soon after preparation. In examining soil or water a series of decimal dilutions was prepared in sterile physiological saline and 1 ml. of each dilution was transferred to each of five tubes of each medium. Incubation was at 30° C. Anaerobic conditions were provided by pyrogallol and sodium carbonate.

Some typical results are shown in Table 1. Iron appears to be at the least as effective as cysteine in promoting the growth of sulphate reducers, and it possesses an advantage over cysteine in not giving rise to false positive results. A finding which greatly simplifies the technique of counting the organisms is that the iron medium may be incubated in air. More than a hundred trials of this medium have been made comparing aerobic with anaerobic incubation; no definite difference could be detected in the results. If the medium containing cysteine were similarly incubated in air the problem of its selectivity for sulphate reducers would arise. A conclusion which may be drawn, incidentally, from this work is that where iron occurs in soil or water into which oxygen penetrates, *Desulphovibrio* could easily find conditions which permitted its growth and its corrosive action on the iron.

Table 1. Influence of Metallic Iron on Growth of Sulphate-reducing Bacteria

Eichornia crassipes in the Nile of the Sudan

During an expedition made by the Hydrobiological Research Unit of the University of Khartoum in March and April 1958, *Eichornia crassipes* was encountered in the White Nile and Bahr el Gebel along about 1,000 km. of the river system. Observations were made in part from the Unit's launch (from Khartoum to the Sobat Mouth) and in the southern reaches (from the Sobat Mouth to Juba) from a Sudan Railways steamer. The latter travelled

Table 1. DISTANCES IN KM. UPSTREAM OF KHARTOUM OF PLACES MENTIONED IN THE TEXT. (Compiled from Sudan Almanac, 1956)

night and day so the southernmost limit of the plant could not be recorded precisely.

Former members of the Hydrobiological Research Unit, Catholic missionaries in the southern Sudan and many Sudanese whose lives are centred on the river agree that they had not seen the plant prior to the winter of 1957–58. Its spread has therefore been of an explosive nature. Recent detailed examination of the photographs which I took in December 1956 on an expedition to the White Nile and Bahr el Ghazal suggests that it may have been present in one or two stations in the Bahr el Ghazal, but this would require confirmation by further field work.

Eichornia occurs either as free-floating mats, as marginally fixed yet floating mats, or as a terrestrial plant of the damp river margins, where it frequently becomes stranded. It reproduces vegetatively by tillers which persist and hold large numbers of individuals together in mats of up to 50 m.^{2}, but usually much less. Its height varies from about 8 cm. to about 40 cm. It flowers abundantly, but the part played by such reproduction was not assessed.

At Kosti (see Table 1) *Eichornia* formed a conspicuous part of the floating marginal vegetation and as drift it was found downstream of the town in small quantities. It occurred from here southwards to the approximate vicinity of Shambe, but its status both as a marginal type and as drifting islands varied considerably, and this variation is analysed briefly below. It was particularly abundant in the Kosti–Gebelein and Malakal–Zeraf Mouth reaches. No drift was seen in, or issuing from, the River Sobat or the Bahr el Ghazal, but as the mouth of the Bahr ez Zeraf was passed in the night no observations can be recorded for that river. The Zeraf Cuts (the artificial capture by the Bahr ez Zeraf of part of the waters of the Bahr el Gebel) are downstream of the most southerly occurrence of *Eichornia* so it is extremely likely that the Bahr ez Zeraf also has the plant.

Eichornia was more common marginally where the river margin was dominated by various Gramineae, especially *Vossia cuspidata*, which advance into the river irregularly, thus creating bays, at least in the season when the river current is slack. Such situations presumably reduce the drag of the river current upon the comparatively loosely attached *Eichornia* mat and were formerly occupied by ecologically similar types, for example, *Pistia stratiotes*, *Azolla* spp. and *Lemna* spp., which in the reaches where *Eichornia* is present have been more or less eliminated. *Eichornia* appears to be the most successful in the competition for this ecological niche.

Its occurrence in relation to swamp types in part explains its distribution in the river system. (1) Upstream of Shambe the river current is strong and papyrus is usually the marginal type. As this species maintains a fairly simple straight front on to the river there are few niches suitable for *Eichornia*. (2) The Kosti–Gebelein and Malakal–Zeraf Mouth reaches are both where the riverain swamp is well developed in a form allowing the marginal attachment and breeding of the plant. (3) The most downstream occurrence (near Kosti) roughly parallels that of papyrus (which is also dispersed in part at least as drift), and downstream of this station the swamps are of a different character, largely owing to the effect of the Gebel Aulia Dam on the amplitude of the river level.

As for all other free-floating river vegetation the distribution pattern of *Eichornia* drift in the river can be related to at least two factors, namely, a source of supply, and a means of bringing plants into the river[1]. Undoubtedly drifting *Eichornia* was more common in, and immediately downstream of, regions where its marginal development was good, but an example will show that its distribution cannot be simply related to a source of supply. At Geigar one evening *Eichornia* drift was abundant; the following morning it was scarce. It is suggested that local storms, so common in the tropics, are an important means of bringing drift into the river and thus explaining its temporal distribution pattern. During one such storm the strong winds and the wave action so induced on the river were seen to break the attachments of marginal *Eichornia* and release it as drift.

The Nile is of vital importance to the Sudan as a line of communication. Already *Eichornia* drift is constituting a minor nuisance to the Sudan Railways steamers by becoming wedged between the driving unit of the steamer and its barges (which are lashed to either side and fore of the driving unit) thus interfering with water intake for engine cooling. Such a nuisance has arisen in the few months that *Eichornia* has been in the Nile. The Congo and many other tropical rivers are witness to the probable result of its continued explosive development.

Chelation or Complex-formation by Indoleacetic Acid *in vitro*

AFTER a long series of attempts to demonstrate chelation or complex-formation between 3-indoleacetic acid and metal ions *in vitro*, which were unsuccessful presumably because of the very low concentrations of indoleacetic acid inevitable in the aqueous solutions used, we repeated the experiments of Cohen *et al.*[1], using, as they did, cupric nitrate and indoleacetic acid in 50 per cent ethanol. Essentially similar results were obtained, except that our value for log K by the Bjerrum method was 3·0 as compared with theirs of 5·4; we were also not entirely satisfied that a discontinuity in our curve for absorption at 360 mμ versus composition occurred at a ratio of 1 copper : 2 indoleacetic acid and there was no indication of a break at 1 copper : 1 indoleacetic acid (*cf.* their Fig. 2).

We also carried out similar experiments with ferric ions, which these authors found to be strongly chelated

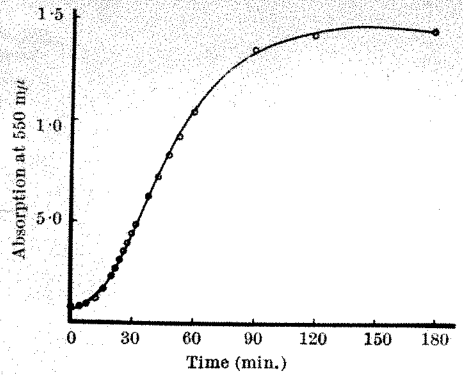

Fig. 1

by 3-indoleacetic acid. The Bjerrum method gave us a value of $\log K$ of 6·0. Measurements of absorption spectra for a solution of 4×10^{-3} *M* ferric chloride and 10^{-1} *M* indoleacetic acid in 50 per cent ethanol showed a strong development of colour, especially between 450 and 600 mμ. It was observed, however, that the intensity of the colour in the mixture increased with time, suggesting either that chelation was very slow or that a progressive break-down of indoleacetic acid to some coloured compound was occurring. The development of colour at 550 mμ in a mixture containing 4×10^{-3} *M* ferric chloride and 2×10^{-3} *M* indoleacetic acid (*p*H 2·6) was measured against time and found to reach a maximum after about 2 hr. (Fig. 1).

To investigate the possibility of break-down of indoleacetic acid, ferric chloride (4×10^{-3} *M*) and indoleacetic acid (2×10^{-3} *M*) were allowed to react in 50 per cent ethanol in Warburg flasks, with shaking, in darkness and at a temperature of 20° C. The output of carbon dioxide and uptake of oxygen with time are shown in Fig. 2. From a similar mixture in a Warburg flask under similar conditions, samples were removed at intervals and tested for indoleacetic acid content by the Salkowski method (Tang and Bonner[2]); the change with time is shown in Fig. 2. It is clear that the presence of ferric ions induced decarboxylation and consequent destruction of almost all the indoleacetic acid with the uptake of an equal volume of oxygen, giving a coloured substance.

Manometric measurements and Salkowski tests on mixtures containing 2×10^{-3} *M* indoleacetic acid and 4×10^{-3} *M* cupric nitrate under the same conditions gave no measurable gas exchange, but 10 per cent break-down of indoleacetic acid occurred over 4½ hr.

Effect of Fumigation and Moisture Content on the Seedling Growth of Cowpea (*Vigna unguiculata*)

It has been shown[1] that the fumigation of maize grain with a 1 : 1 mixture of ethylene dichloride and carbon tetrachloride adversely affects the growth of seedlings raised from the grain. Similar results have now been obtained from a study of the early growth of cowpeas raised from fumigated seed.

A supply of cowpea was obtained which had a moisture content of 12 per cent, and half was dried to a moisture content of 10 per cent by spreading out in a room with a low atmospheric humidity. Two 2-lb. jars were filled with seed at each moisture content, and one of each of these was fumigated with a 1 : 1 mixture of carbon tetrachloride and ethylene dichloride at a concentration of 20 cm.^{3} of total storage volume. All the jars were sealed and after two months they were opened and 30 seeds from each of the two treatments and two controls were taken and planted 10 per pot in 8-in. pots filled with garden soil. Eleven days after sowing, the plants which had grown were removed and their fresh weights determined (Table 1).

From a comparison of the results for the two control series it is evident that drying the seed to the lower moisture content had a retarding effect on early growth. Most plants grown from seed of 12 per cent moisture content were more than 2·0 gm. in weight, whereas most of those from seeds with a moisture content of 10 per cent weighed 1·1–1·4 gm. at the end of the experiment.

The effect of fumigation was particularly noticeable with seedlings arising from seeds with the higher moisture content; a quarter of the seedlings in this group weighed less than 0·2 gm. Plants grown from seeds with the lower

moisture content did not appear to suffer so drastically from fumigation though their general growth was retarded.

It seems likely from work still in progress that the retardation of growth in seedlings from seeds with the lower moisture content is only temporary and will not affect the ultimate yield. However, the severe retardation observed for about a quarter of the plants grown from the moister seeds that had been fumigated is likely to be permanent, the seedlings being deformed and only slowly, if ever, reaching maturity.

The above results stress the need for measuring growth and yield as well as germination when considering the effect of fumigants on stored seed to be used for planting.

An Age Effect on Seta Elongation in *Pellia epiphylla*

IN a recent communication, Asprey *et al.*[1] report that spraying with indolylacetic acid and gibberellin effects elongation of the setæ of *Pellia epiphylla* in January, whereas under normal conditions this is delayed until late February or early March. We have obtained results which suggest that during the winter months a gradual change occurs, bringing setæ into a condition when they are capable of rapid elongation once the temperature is raised. In view of the results of Asprey *et al.*, this internal change may well be correlated with synthesis of growth hormones.

Table 1. EFFECTS OF AGE, RISE IN TEMPERATURE AND EXTRA LIGHT ON SETA ELONGATION

Time (weeks) from collecting material until 50 per cent of the setae started to elongate

Treatment	Date collected					
	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.
15° C., normal light	20	14·5	8	5·5	2·5	0·5
15° C., normal light*	21	14	9	—	—	—
15° C., normal light + 10 f.c. tungsten light for 16 hr. each day	—	10	6·5	4·5	2	0·5
15° C., normal light + 10 f.c. tungsten light for 16 hr. each day*	15	9·5	7	—	—	—

* Kept 2 weeks at 1° C. immediately after collection.

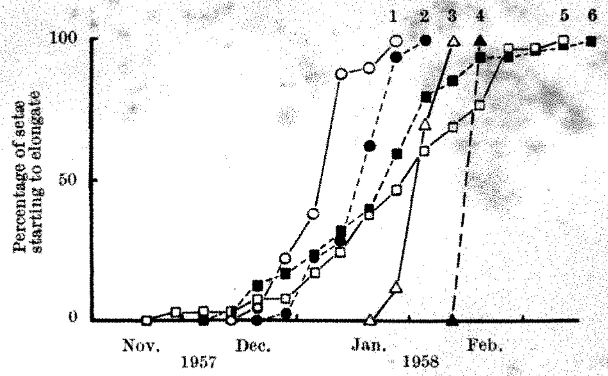

Fig. 1. Effect of age on the ability of setæ to elongate when transferred to 15° C. Material in the field showed no seta elongation until March 1958. Dates transferred: 1, November; 2, December; 3, January; 4, February; 5, September; 6, October

Fresh material of *Pellia epiphylla* was collected from a site near Southampton at intervals from mid-September 1957 to February 1958 and kept in a warm greenhouse (mean temperature 15° C., minimum 10° C.). The number of setæ elongating was counted at weekly intervals and the capsule contents also examined. Fig. 1 shows that rise in temperature promotes seta elongation in every case (material left in the field did not start to elongate until March 1958), but the most marked effect is that of age of the sporophyte. This is shown more clearly in Table 1, which records the lag period before 50 per cent of the setæ start to elongate. Two weeks cold treatment (1° C.) given immediately after material had been collected did not affect the results, but provision of extra light shortened the lag period slightly. It is tentatively suggested that during the winter there is a slow synthesis of growth hormones (or removal of a growth inhibitor), which is stimulated to some extent by a rise in temperature and extra light. The fact that the maximum length reached by setæ was considerably less in samples collected early in the season would also support this idea. It would be of particular interest to know if indolylacetic acid and gibberellin are effective in promoting seta elongation in material collected in the autumn.

Subsidiary observations were made on spore development, since it has been suggested that maturation of the spores is the stimulus for seta elongation. Under normal conditions the tetrads divide into spores at the end of November, but material collected in September and October before this change had occurred and kept at a warm temperature, had not formed spores by March 1958, when observations were discontinued. Despite immaturity of the spores seta elongation occurred (Table 1), and it is therefore highly improbable that there is a direct relationship between spore maturation and seta elongation. A similar conclusion was reached by Asprey *et al.* from their experiments. A further observation supporting this was that two weeks cold treatment was effective in stimulating tetrad division in material collected in October, but seta elongation was unaffected.

Nematoses of Pyrethrum in East Africa

Dalmatian pyrethrum (*Chrysanthemum cinerariaefolium*) (Trev.) Vis. is widely attacked in Kenya and Tanganyika by species of the nematode genus *Meloidogyne* Goeldi (root-knot nematodes), in particular *Meloidogyne hapla* Chitwood, 1949, which is a new host record.

Interveinal chlorosis and necrosis of the leaf lamina are invariably associated with heavy leaf populations of *Aphelenchoides ritzema-bosi* (Schwartz) Steiner.

While considerable economic importance must be attached to root galling of commercial pyrethrum by *Meloidogyne* spp., a recently discovered root-rot disease associated with high root populations of an apparently new species of the genus *Pratylenchus* Filipjev may prove of equal importance in pyrethrum farms at altitudes between 7,000 and 9,000 ft. This disease, although suspected in several areas of Kenya, was first found on a two-year-old planting at 8,500 ft. near Limuru, Kenya. Of 72 random samples of roots with surrounding soil, collected in groups of 24 at bi-monthly intervals from three adjacent terraces of very stunted plants, 57 were affected by a root-rot disease, with which *Pratylenchus* n.sp. was invariably associated. Heavy attacks of *M. hapla* were also present but not correlated with the symptoms of root-rot.

The first sign of this root-rot is the appearance of small patches of a brownish discoloration on the root epithelium. These lesions increase in area, darken and penetrate to the stele, girdling and eventually producing an almost completely blackened root. Eggs, larvæ and adults are found in affected tissue, specimens being recoverable even from the smallest lesions. Other nematodes and fungi are found in the later stages of the disease but not apparently in the early lesions.

Although *Pratylenchus* spp. have been reported in species of *Chrysanthemum* (Tourn.) L.[1-4] invasion and reproduction in the roots of *C. cinerariaefolium* by *Pratylenchus* n.sp. constitutes a new host record. A detailed description of the parasite will be published elsewhere.

Heavy Infestation by the Parasitic Copepod *Lernaeenicus* of Sprats in the River Crouch

Whitebait sprats in the estuary of the River Crouch collected in May 1957 were found to be heavily infested with copepod parasites. The fishes were collected by using a 12-ft. beam trawl with shrimp netting, several hauls being made between Burnham-on-Crouch and Holiwell Point, just inside the mouth of the River Crouch in Essex. Of the 140 sprats (*Culpea sprattus*) captured, 43 (31 per cent) were afterwards found to be parasitized by the copepod *Lernaeenicus*. The two British species of this genus, *L. sprattae* and *L. encrasicola*, were both present. It is a general rule that *L. sprattae* is fixed in the eye of the fish while *L. encrasicola* has its head buried in the tissues of the body, usually in the back, and the present sample was no exception to this rule. The sprats may be divided into the following categories :

97 sprats with no copepod parasites
32 sprats with one *L. sprattae* in one eye
2 sprats with two *L. sprattae* in one eye
7 sprats with one *L. encrasicola* in the back
1 sprat with two *L. encrasicola* in the back
1 sprat with one *L. sprattae* in an eye and one *L. encrasicola* in the back

L. sprattae is most easily distinguished from *L. encrasicola* by the moniliform appearance of the neck, as can be seen in Fig. 1. There is no doubt that the present infestation of more than 30 per cent of the fish is a severe one, but there are very few records in the literature which give a definite indication of the number of sprats parasitized in a sample. Leigh-Sharpe[1] gives 3 per cent infestation for two samples taken at Hole's Hole, near Plymouth, independently by himself and Dr. R. Gurney in 1934, and he quotes T. Scott and A. Scott's[2] earlier figure of 2·3 per cent at Plymouth in 1910. Among Gurney's manuscript papers now in the British Museum there is a note directing attention to the remarkable fact that his specimens of *Lernaeenicus* from Hole's Hole, from more than 1,000 fishes, collected on April 10, 1934, were young, not one of them being fully grown or bearing eggs, while Leigh-Sharpe's specimens from 970 sprats, collected from the same place in the spring of the same year, presumably a little later though the actual date is not known, were mature and bearing eggs. A rapid growth of the parasite is indicated, with presumably an adverse effect on the host.

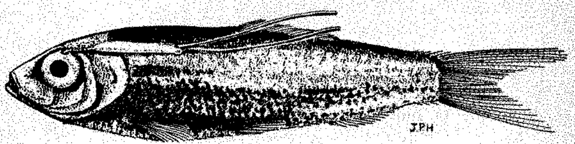

Fig. 1. A sprat about 5 cm. long with a parasite (*Lernaeenicus sprattae*) embedded in the eye. Note the hole in the eye, the moniliform shape of the neck and the two long strings of eggs which stream out from the hinder end of the cylindrical body of the parasite

In the rather overcrowded conditions of fish farms in hot countries, infestations of the fishes by the similar copepod *Lernaea* sometimes occur which are more severe than any known under natural conditions ; Nakai[3] describes eels and loaches with the buccal cavity so crowded with parasites that food could not be swallowed. Very little, however, is known about the effect on fishes, under natural conditions, of copepod parasites of this type which live with the head buried in the tissues of the host, presumably feeding on blood and other fluid tissues. It was thought that with such a large sample of fish, both with and without parasites, it would be easy to detect signs of unhealthiness in the parasitized fishes, but this was not so, even statistically. The shape-index (S) was calculated for each fish using the formula $S = K \frac{\sqrt[3]{w}}{l}$ where w is the weight in gm., l the standard length in cm., and K is a constant. For fishes of the same length, the greater the weight the greater the shape-index. Each of 138 fishes was measured individually to the nearest mm. and weighed to the nearest 10 mgm., two of the original sample were discarded owing to damage, one of them parasitized. The value of K used (5·14) is such that a normal fish has the shape-index of 1·0, in other words, of the 138 fishes measured, 69 had an index of less than 1·0 and 69 greater than 1·0. The shape-index of each fish is plotted against its length in Fig. 2. On the left side of the figure are the fishes without parasites and on the right, for comparison, are the smaller number with parasites. The pattern of distribution shown in this figure is substantially the same for both groups of fishes. Of the 42 parasitized fishes measured, 25 had a shape index greater than, and 17 less than, unity; and of the 96 healthy fishes 44 had an index greater than, and 52 less than, unity. This would indicate a beneficial effect of the parasite on the weight of the fish, but the difference is slight and probably not statistically significant.

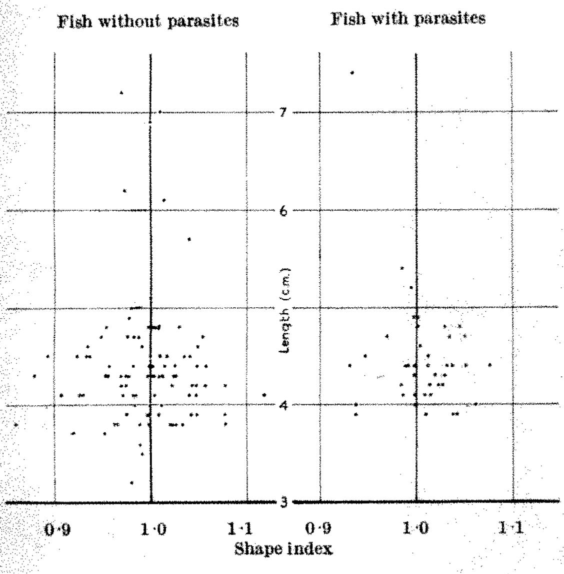

Fig. 2. Shape index and length distributions of parasitized and normal fishes

The lengths of the fishes shown in Fig. 2, varying from 3·2 to 7·4 cm. in standard length, fall within the size range given by Robertson[4] for samples of whitebait sprats from the Thames Estuary, which he considered to be mainly composed of 0-group fishes. The considerable size-range is probably a reflexion of the prolonged spawning season of sprat in the North Sea—March to August (maximum in June); and the few large fishes, one of which was parasitized, were probably spawned early in the season and were thus 1-group or close to it when caught. This conclusion, which is in conformity with Robertson's findings, was supported by an examination of the few scales present on two of the large sprats which appeared to be those of 1-group fishes.

Movement of Salmon on the River Erne

A graphic record of salmon (*Salmo salar*) ascending the fish pass at Cathaleen's Fall Hydro-Electric Generating Station has been kept for four fishing seasons. This station is one of two erected by the Electricity Supply Board, Ireland, on the River Erne. It is located at the toe of a dam across the river and has an installed capacity of 45,000 kW. and a gross head of approximately 100 ft.

The fish ladder extends from the power station tailrace over the dam into the head waters. The tailrace is tidal. The ladder is of the White submerged-orifice type similar to those developed and used by the North of Scotland Hydro-Electric Board at its Pitlochry and Clunie power stations. It has 73 pools with a difference in water-level of 1½ ft. between successive pools. Some of the bottom pools are, however, submerged except at low tide or when the turbines in the power station are not operating; some of the top pools are by-passed at low reservoir levels. Orientation of the pass is approximately east–west.

The counter is of the nylon-screen type developed by the Board and has as an accessory a recording voltmeter which shows on a chart the time of the passage of each fish through the counter.

A preliminary analysis of the results so far available indicates the following movements of salmon: (*a*) an almost complete cessation of activity during hours of darkness; (*b*) greatest activity between noon and dusk; (*c*) the number of fish travelling singly is small in comparison with the total count.

Pigmy Sperm Whale (*Kogia breviceps*) in Borneo

In recent years the Sarawak Museum has developed a system by which people along the west coast of Borneo report (if they have time) the occurrence of any beached cetacean. Partly by this means, and with the help of Malays and Dayaks, we have extended the local list from five to fourteen known forms in the past five years, advised and criticized by Dr. F. C. Fraser, of the British Museum (Natural History).

In 1956, and again in 1957, complete examples of the comparatively rare Bryde's whale (*Balaenoptera brydei*) were obtained in this way, and on February 19, 1958, we were able to recover from Buntal in south-west Sarawak, a perfect specimen of the very little-known pigmy sperm whale (*Kogia breviceps*). This miniature 10-ft. version of the sperm whale—the greatest of all the toothed cetaceans—has not previously been recorded from this part of the world. Of added interest was the presence of a well-developed embryo. A beautiful baby, of a battleship-grey, it is 14½ in. long. Two of seven previously recorded embryos are from European waters.

Photographs and measurements have been sent to the British Museum (Natural History) for confirmation of identification.

Borneo.

FORTHCOMING EVENTS

Wednesday, August 27—Wednesday, September 3

British Association for the Advancement of Science (at Glasgow).—Annual Meeting.

Wednesday, August 27

At 7.15 p.m.—Sir Alexander Fleck, F.R.S.: "Science and Business: a Balanced Partnership" (Presidential Address).

Thursday, August 28

At 10 a.m.—Prof. H. J. Emeléus, F.R.S.: "The Chemistry of the Transuranic Elements" (Presidential Address, Section B).

At 10 a.m.—Dr. A. S. Parkes, F.R.S.: "Some Biological Effects of Low Temperatures" (Presidential Address, Section D).

At 10 a.m.—Prof. R. S. Adamson: "The Cape as an Ancient African Flora" (Presidential Address, Section K).

At 10 a.m.—Dr. D. P. Cuthbertson: "Digestion in the Ruminant" (Presidential Address, Section M).

At 11.15 a.m.—Prof. H. M. Steven: "The Native Pinewoods of Scotland and their Significance for Current Forestry Practice" (Chairman's Address, Section K*).

At 11.30 a.m.—Prof. R. W. Bickford: "A Review of Some Problems of Colour Vision and Colour Blindness" (Presidential Address, Section J).

At 2.15 p.m.—The Rt. Hon. Lord Boyd Orr, F.R.S.: "The Cultural Value of Local Societies" (Presidential Address, Section X).

Friday, August 29

At 10 a.m.—Prof. E. Estyn Evans: "The Atlantic Ends of Europe" (Presidential Address, Section E).

At 10 a.m.—Prof. A. J. Brown: "Inflation and the British Economy" (Presidential Address, Section F).

At 10 a.m.—Prof. O. A. Saunders, F.R.S.: "Heat and the Engineer" (Presidential Address, Section G).

At 11.30 a.m.—Sir Willis Jackson, F.R.S.: "The Partnership between Industry and Education" (Presidential Address, Section L).

At 8 p.m.—Sir Christopher Hinton, F.R.S.: "Nuclear Power and the Engineer" (Evening Discourse).

Sunday, August 31

At 11 a.m. (in Glasgow Cathedral)—Religious Service. Preacher: The Reverend Dr. Nevile Davidson, Minister of Glasgow.

Monday, September 1

At 10 a.m.—Dr. T. E. Allibone, F.R.S.: "Some Aspects of Thermonuclear Power" (Presidential Address, Section A).

At 10 a.m.—Prof. L. R. Wager, F.R.S.: "Beneath the Earth's Crust" (Presidential Address, Section C).

At 10 a.m.—Dr. Iorwerth C. Peate: "The Study of Folk Life and Its Part in the Defence of Civilization" (Presidential Address, Section H).

At 10 a.m.—Dr. E. N. Willmer: "Some Aspects of Cellular Differentiation" (Presidential Address, Section I).

At 8 p.m.—Dr. C. F. A. Pantin, F.R.S.: "Living Machinery and the Electron Microscope" (Evening Discourse).

Wednesday, August 27—Wednesday, September 3

The Combustion Institute, in collaboration with the Institute of Fuel (at the Royal Institution of Great Britain, 21 Albemarle Street, London, W.1, and at Oxford)—Seventh International Symposium on "Combustion".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Assistant (with a degree in agriculture with special reference to animal husbandry or production), for investigations on carcase quality of beef—The Secretary, School of Agriculture, The University, Cambridge (September 8).

Junior Research Fellow in Geography—The Registrar, The University, Sheffield (September 13).

Lecturer/Senior Lecturer (preferably with a special interest in morphological, physiological or chemical cytology) in Histology and Embryology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 13).

Assistant Experimental Officer (with a degree or diploma in agriculture or botany and preferably a knowledge of potato varieties) in the Virus Diseases Section—The Secretary, Scottish Plant Breeding Station, Pentlandfield, Roslin, Midlothian (September 15).

Assistant Lecturer (with special qualifications in applied mathematics) in Mathematics—The Registrar, The University, Manchester 13 (September 15).

Lecturer in Pure Mathematics—The Registrar, The University, Hull (September 15).

Senior Lecturer or Lecturer in Physics at the University of Khartoum, Sudan—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 22).

Assistant Lecturer in Botany—The Registrar, The University, Manchester 13 (September 30).

Chair of Logic and Metaphysics—The Secretary to the Curators of Patronage, The University, 4 Albyn Place, Edinburgh 2 (September 30).

Director (academically well qualified, of proven scientific leadership and administrative ability) of the Cawthron Institute, Nelson, New Zealand, to develop researches primarily into plant nutrition problems of horticulture and agriculture—The Managing Secretary, Cawthron Institute Trust Board, Box 29, Nelson, New Zealand or the N.Z. High Commissioner, 415 Strand, London, W.C.2 (New Zealand, September 30).

Lecturer in Inorganic Chemistry at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 30).

Research Officer (preferably with a good university honours degree in physics, or mathematics, with postgraduate research experience) in the Division of Meteorological Physics, C.S.I.R.O., Aspendale, Victoria, Australia, to participate in a programme of research into the micro-meteorological aspects of various agricultural problems with special emphasis on the study of evaporation from natural surfaces—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 420/127 (September 30).

Chair of Soil Science in the Institute of Agriculture, University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 8).

Lecturer in Psychology at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Lecturer/Senior Lecturer in Pathology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Assistant Experimental Officer (with a degree in chemistry or agricultural chemistry), to carry out chemical analyses of soils and plants—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Assistant Lecturer (with an honours degree and interested in research work) in the Botany Section of the School of Pharmacy—The Secretary, Royal College of Science and Technology, Glasgow.

Head (with high academic qualifications in mathematics, teaching and research or industrial experience, and preferably specialized in statistics and/or numerical analysis) of the Department of Mathematics—The Principal, College of Technology, Queen Street South, Huddersfield.

Plant Pathologist (male, with a good honours degree in agriculture or natural science, at least one years postgraduate training in mycology and plant pathology, and preferably a knowledge of virus diseases) in the Department of Agriculture, Tanganyika, for field and laboratory work in the diagnosis and investigation of fungal and bacterial diseases of crop plants and the testing of control measures—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/8/08.

Principal Fisheries Research Officer (with a good honours degree in zoology and considerable postgraduate experience in fisheries research) with the Federation of Nigeria, to lead a small group of scientists and technicians in either sea fisheries research or inland fisheries and fish culture research—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/14/03.

▶ Research Assistant (with the B.Sc. (Special Chemistry) Degree of the University of London) in Chemistry—The Registrar, Brighton Technical College, Brighton, Sussex.

Senior Technician and other technical staff, for work upon steroid hormone assays in relation to gynaecology—The Director of the Endocrine Unit, Chelsea Hospital for Women, Dovehouse Street, London, S.W.3.

Technician or Junior Technician in the Histopathology Department—The Director of Pathology, Chelsea Hospital for Women, Dovehouse Street, London, S.W.3.

Tsetse Officers (male, under 30, with a good honours degree in biology) in Tanganyika, for tsetse surveys and subsequently to advise on anti-tsetse measures—The Director of Recruitment ,Colonial Office, London, S.W.1, quoting BCD.63/8/022.

Inside Story

ENDECOTTS
TEST SIEVES

No crevices to trap particles ; frame and wire cloth are joined as one.

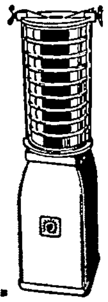
Guaranteed Accurate Manufactured under licence from the British Standards Institution.

Mechanical Sieving is ideal with Endecotts Sieves—several simultaneous tests are possible with intermediate receiving pans.

British, U.S. Standards and Tyler Equivalents are readily available, many other international standards also supplied.

"Endrock" Test Sieve Shaker saves valuable time and effort of skilled personnel; similar to manual motion but is more consistent, having a regular mechanical action—a time switch controls the length of time for tests.

We operate a **Recovering Service**—if sieving is important to your business, ring or write for literature—or for any advice you require—we'll be glad to help.



ENDECOTTS (FILTERS) LTD.
251 Kingston Road, Merton Park, London, S.W.19.

New Books

SCIENCE in SCHOOLS

Edited by W. H. PERKINS, O.B.E.
for the British Association for the Advancement of Science

Learning before luxury ? Should schools receive a better share of the scientists who are graduating to-day ? Science as an also-ran in girls' grammar schools ? Just one period a week of nature study for primary school science ? , How are we spending now . . . how much . . . how quickly should we expand ?

These and other topical questions on science education were discussed by certain leading industrialists, scientists, and educationalists of our day at the April, 1958, British Association Meeting. The papers now appear in eminently readable book form. They will be of interest to all who believe that the development of science and technology cannot take place without a much bolder programme of rapid educational advance than any which has yet been promulgated.

Price 15*s*.

ESSENTIAL FATTY ACIDS

Editor: H. M. SINCLAIR

Some thirty years ago it was shown that certain unsaturated fatty acids are needed in the diet of rats and therefore constitute vitamins. In the last year or two it has been found that these acids lower serum cholesterol and that deficiency of them may be relevant to certain very important clinical conditions such as atheroma and coronary thrombosis.

Our understanding of the structure and synthesis of fatty acids has increased enormously in recent years. Their chemical, biochemical and clinical aspects were thoroughly discussed at the Fourth International Conference on Biochemical Problems of Lipids and this volume of 42 edited papers adds considerably to current knowledge of this rapidly advancing subject.

September, 1958. *Price* 50*s*.

AUTOMATIC MEASUREMENT of QUALITY in PROCESS PLANTS

Editors: SOCIETY OF INSTRUMENT TECHNOLOGY

These edited papers of The Society of Instrument Technology 1957 Conference provide a valuable and objective survey of the various techniques available for the quality control process plants. They fall into two complementary groups ; those covering a survey of the experience which has been gained with the wide variety of control instruments already in general use, whole of the second group explores the potential plant application of analytical techniques currently in use in the laboratory.

Price 50*s*.

Fully descriptive leaflets available, post free, from

BUTTERWORTHS SCIENTIFIC PUBLICATIONS
4 & 5 Bell Yard, London, W.C.2

LECTURES AND COURSES

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S.W.3
DEPARTMENT OF CHEMISTRY
SESSION 1958-59

Head of Department: J. F. J. Dippy, D.Sc., F.R.I.C.

Recognized Day and Evening Courses leading to B.Sc. degrees (London, Internal), and the Graduateship and the Diploma (Food and Drugs) of the Royal Institute of Chemistry, commence on Monday, September 22, 1958. Various postgraduate courses are also available.

Full particulars on application to the Secretary.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S.W.3
DEPARTMENT OF CHEMISTRY
SESSION 1958-59

A course of 20 postgraduate lectures on "Biochemistry" (to be arranged in four groups) will be given by Dr. E. M. Crook, M.Sc., and Professor F. L. Warren, M.A., D.Sc., on Mondays, 7.15 to 8.30 p.m., during the period October 6, 1958, to March 16, 1959. The course is designed for students who possess a knowledge of chemistry to degree standard. Fee: £2 for whole course or 10s. for each group.

A leaflet giving details is obtainable from the Secretary.

THE POLYTECHNIC

309 REGENT STREET, W.1
DEPARTMENT OF MATHEMATICS AND PHYSICS

The following courses of lectures have been arranged, starting in September, 1958:

1. A SECOND COURSE ON ELECTRONICS on Monday evenings, 6.30 to 8.30 p.m.
2. MODERN ELECTRIC NETWORK THEORY on Friday evenings, 7 to 9 p.m.

Full particulars may be obtained on application to the Director of Education.

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF CIVIL AND MUNICIPAL ENGINEERING
COURSE IN PHOTOELASTICITY, 1958/59

This course extends over the academic year, commencing on September 29, 1958, and comprises weekly lectures on the theory and methods of photoelasticity with particular emphasis upon the use of photoelastic methods in practical stress-analysis problems. A few places are also available for students taking the course who are able to spend one or two days a week on practical work in the laboratories. The course is suitable for workers in industrial research laboratories or for teachers in engineering colleges who wish to obtain a practical knowledge of the subject. The times of lectures and laboratory periods will be arranged, as far as possible, to suit the requirements of students.

Fees: Lectures, £14. Laboratory work, 1 day per week, £11; 2 days per week, £16.

Those wishing to attend the course should make early application as laboratory accommodation is strictly limited. Application should be made to The Secretary, University College London, Gower Street, W.C.1.

OFFICIAL APPOINTMENTS

COUNCIL FOR TECHNICAL CO-OPERATION IN SOUTH AND SOUTH-EAST ASIA

Applications are invited by the Foreign Office for the following appointments at the University of Rangoon, Burma, under the Technical Co-operation Scheme of the Colombo Plan: 1. Senior Lecturer in Chemical Engineering. 2. Senior Lecturer in Metallurgy. Will be required to teach up to degree level. Should hold a higher degree in chemical engineering or metallurgy (as appropriate) and have had at least five years' teaching and research experience. Duration two years. Contract with the U.K. Government. Salary, £2,000 per annum (subject to U.K. income tax), plus tax-free oversea allowance of £1,600 per annum (less for a single man) and other allowances. Free furnished accommodation provided.

For further information and application forms, write Ministry of Labour and National Service (E.9), 26-28 King Street, London, S.W.1, quoting E9/TCS/236-7/BUR.

COUNCIL FOR TECHNICAL CO-OPERATION IN SOUTH AND SOUTH-EAST ASIA

Applications are invited by the Foreign Office for the following appointments at the University of Rangoon, Burma, under the Technical Co-operation Scheme of the Colombo Plan: 1. Lecturer in Mechanical Engineering. 2. Lecturer in Mining Geology. Should preferably hold a higher degree with, in addition, at least three years' practical experience in the case of 1. and, at least five years' field experience or three years' teaching experience, in the case of 2. 3. Lecturer in Architecture. Must have degree in Architecture or A.R.I.B.A., with at least five years' professional experience, preferably in the tropics. In all cases will be required to teach up to degree level. Duration two years. Contract with the U.K. Government. Salary £1,650 per annum (subject to U.K. income tax), plus tax-free oversea allowance of £1,360 per annum for married man (less for a single man) plus other allowances. Free furnished accommodation provided.

For further information and application form write Ministry of Labour and National Service (E.9), 26-28 King Street, London, S.W.1, quoting E9/TCS/234-5-8/BUR.

NATIONAL RESEARCH DEVELOPMENT CORPORATION

Applications are invited for the position of Managing Director of the Corporation. The Development of Inventions Acts, 1948 and 1954, under which the Corporation operates, provide for the appointment to be made by the Board of Trade. The Board will consider all applications in consultation with the Chairman of the Corporation. The appointment will be subject to the conditions set out in the National Research Development Corporation Regulations, 1949, and will run for a period of three years from April 1, 1959, in the first instance. The salary is £5,000 a year and a contributory pension scheme is available. High level administrative experience is required, together with wide knowledge of the sciences and their industrial application, or proved ability to provide administrative leadership for a technological team. Information about the Corporation can be obtained from its Annual Report published by H.M. Stationery Office, or by writing to the Secretary of the Corporation at 1 Tilney Street, W.1.

Three copies of each application, giving age, qualifications and experience, should be sent to the Secretary, Board of Trade, Horse Guards Avenue, S.W.1, before October 13, 1958, the envelope being marked "N.R.D.C. Application."

UNIVERSITY OF CANTERBURY

CHRISTCHURCH, NEW ZEALAND
LECTURER IN INORGANIC CHEMISTRY

Applications are invited for the above position. The salary range is £1,025 to £1,275, rising by £50 annual increments and the initial salary will depend on qualifications and experience. An allowance is made towards travelling expenses.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications in New Zealand and London is September 30, 1958.

ROYAL NAVAL SCIENTIFIC SERVICE REquires Senior Scientific Officers and Scientific Officers for Establishments in London area, Baldock, Portsmouth, Portland, Poole, Greenock and Rosyth. Main requirements are about 25 vacancies for Physicists, Electronic Engineers and Mathematicians in areas specified. The following particular vacancies also exist: Mechanical Engineer for work on gas turbine problems in the London area. Mechanical Engineers for work on design and development of U/W devices in Portland area. Metallurgists for Rosyth and Poole. Chemists (Physical and Inorganic) for Poole area, Baldock and London. Candidates must normally be natural born British subjects of natural born British parents, with at least first- or second-class honours degrees or equivalent high professional attainments. Senior Scientific Officers must have had at least three years' postgraduate experience and be not less than 26 years of age. Salaries (men): Senior Scientific Officer, £1,190 to £1,410; Scientific Officer, £635 to £1,110 (London)—somewhat lower in provinces. Appointments unestablished (with F.S.S.U. benefits), but opportunities may occur for those between the ages of 21 and 32 to compete for established posts.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A98/8A.

KUMASI COLLEGE OF TECHNOLOGY

(Principal: W. E. Duncanson, Ph.D., D.Sc., F.Inst.P., A.M.I.E.E.)

Applications are invited for the posts of Senior Lecturers and Lecturers in the Department of Mechanical Engineering. The College prepares students for the London University B.Sc. degree in Engineering and for the examinations of the professional Engineering Institutions. Applicants should have a degree or equivalent qualifications with suitable teaching and professional qualifications. Duties will involve some of the following: teaching of Strength of Materials and Metallurgy, Theory and Design of Machines, Engineering Drawing; taking charge of applied Thermodynamics Laboratory. Appointment may be accepted on contract for five years or on pension or arrangements to continue policies initiated under the F.S.S.U. Scheme might be made by the College. Contract salary scales: Senior Lecturer, £2,125 by £75 to £2,425 per annum; Lecturer, £1,271 5s. by £62 10s. to £2,031 5s. plus a gratuity payable at the end of contract at the rate of £12 10s for each month of satisfactory service. Pensionable and F.S.S.U. salary scales: Senior Lecturer £1,580 by £60 to £1,940; Lecturer £925 by £50 to £1,625. Point of entry according to experience. Children's allowances up to a maximum of three at the rate of £50 per annum per child up to 10 years and £100 per annum per child over 10 years in full-time education up to 21 years. Annual leave with free return first-class passages for the member of staff and conditional on a minimum stay in West Africa, for his wife and up to three children under 17 years. Bungalows with basic furniture at low rental are provided. Income tax low.

Applications (six copies), giving age, qualifications, experience and the names of three referees, should be sent to the Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2. Closing date: September 5, 1958.

KUMASI COLLEGE OF TECHNOLOGY

(Principal: W. E. Duncanson, Ph.D., D.Sc., F.Inst.P., A.M.I.E.E.)

Applications are invited for the following appointments: (a) Senior Lecturer or Lecturer in Electric Power Machines; (b) Senior Lecturer and Lecturer in Electrical Engineering. The College prepares students for the London University B.Sc. degree in Engineering and for the examinations of the professional Engineering Institutions. Qualifications: Good honours degree; A.M.I.E.E., or equivalent professional qualification; industrial and teaching experience in the case of those applying for the Senior Lectureships. Appointment may be accepted on contract for five years or on pension. Arrangements to continue policies initiated under F.S.S.U. Scheme might be made by the College. Contract salary scales: Senior Lecturer, £2,125 by £75 to £2,425 per annum; Lecturer, £1,281 5s. by £62 10s. to £2,031 5s. per annum; plus gratuity payable at end of contract at the rate of £12 10s. for each month of satisfactory service. Pensionable and F.S.S.U. salary scales: Senior Lecturer, £1,580 by £60 to £1,940 per annum; Lecturer, £925 by £50 to £1,625 per annum. Point of entry according to experience. Children's allowances up to a maximum of three at the rate of £50 per annum per child up to 10 years, and £100 per annum per child over 10 years in full-time education up to 21 years. Annual leave with free return first-class passages for member of staff and, conditional on minimum stay in West Africa, his wife and up to three children under 17 years. Bungalows with basic furniture at low rental provided. Income tax low.

Applications (six copies), giving age, education, qualifications, experience and the names of three referees, should be sent to the Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2. Closing date September 5, 1958.

UNIVERSITY COLLEGE

IBADAN, NIGERIA

Applications are invited for Lectureship (Grade I or II) in Zoology from candidates with interests in entomology or physiology. Initial appointment three years. Salary scales: Grade I, £1,400 by £50 to £1,650 per annum; Grade II, £1,000 by £50 to £1,300 per annum. Passages paid for appointee, wife and three children under 11 years on appointment, annual overseas leave and termination. Children's, car, and outfit allowances. F.S.S.U. Part-furnished accommodation.

Detailed applications (six copies), naming three referees, by September 30, 1958, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

COMMONWEALTH of AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF ELECTROTECHNOLOGY

APPOINTMENT OF PHYSICISTS

Applications are invited for appointment to one of two positions of Physicist with the Organization's Division of Electrotechnology. The Division, comprising a staff of forty scientists and thirty ancillary staff, is located in the University Grounds, Sydney, and is engaged in research in the field of electrical standards of measurement and allied subjects such as dielectrics research and microwave spectroscopy. The two positions available are: (a) Dielectrics Research. The appointee will be a member of a group of seven scientists engaged in dielectrics research. Adequate opportunity will be available for the appointee to develop an individual research programme. Applicants should possess a university honours degree in physics and some postgraduate research experience. Experience in some branch of solid state physics would be desirable. (b) Radio Frequency Measurements. Initially the appointee would be engaged on research in the frequency range 200 to 2,000 Mc./s, to develop precise power measuring techniques in the very low power range. However, ample opportunities will be given for the appointee to develop an individual research programme in precise radio frequency measurements or an allied field. Applicants should hold a university honours degree in physics with postgraduate research experience. Dependent upon qualifications and experience, commencing salary for each position will be determined within the salary ranges of Research Officer, £A.1,326 to £A.1,951 per annum or Senior Research Officer, £A.2,061 to £A.2,336 per annum. Salary for a female appointee would be £A.170 per annum, less than the corresponding male rates. Appointment will be conditional upon a satisfactory medical examination. The Appointments will be for an indefinite period or for a period of three years, at the option of the appointees. Confirmation of appointment for an indefinite period carries with it Commonwealth Superannuation Fund or Commonwealth Provident Account privileges. Fares to Australia, including those of wife and dependent family, will be provided by the Organization, and, in the case of appointment for a fixed period, return fares to point of origin will be allowed for an appointee who is not of Australian nationality. Details may be discussed with the undersigned.

Applications, quoting Appointment No. 760/106 and stating full name, place, date and year of birth, nationality, marital state, present employment, details of qualifications and experience, and of war service if any, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach the undersigned, from whom further particulars may be obtained, by September 26, 1958.

E. J. DRAKE,
Chief Scientific Liaison Officer.
Australian Scientific Liaison Office,
Africa House, Kingsway, London, W.C.2.

UNIVERSITY OF GLASGOW

ASSISTANTSHIP IN BOTANY

Applications are invited for an Assistantship in Botany. Salary scale: £700 to £850. Initial salary according to experience and qualifications. F.S.S.U. and family allowance benefits.

Applications (three copies) should be lodged not later than August 30, 1958, with the undersigned, from whom further particulars may be obtained.

ROBT. T. HUTCHESON,
Secretary of University Court.

UNIVERSITY OF SYDNEY

AUSTRALIA

LECTURESHIP/SENIOR LECTURESHIP IN PATHOLOGY

Applications are invited for the above position. The salary for a Senior Lecturer is within the range £A.2,200 by £A.80 to £A.2,550 per annum; for a Lecturer within the range £A.1,500 by £A.90 to £A.2,100 per annum. In each case cost of living adjustment will be allowed. The salary is subject to deduction under the State Superannuation Act. The commencing salary will be fixed according to qualifications and experience of the successful applicant. Under the Staff Members' Housing Scheme, in cases approved by the University and its Bankers, married men may be assisted by loans to purchase a house

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close, in Australia and London, on October 31, 1958.

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

(Faculty of Technology in the University of Manchester)

RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant in the Department of Physics. The person appointed will be required to take part in the research of the Department which is at present concerned with X-ray diffraction, physical optics, electronics and instrumentation, and will be expected to become a candidate for the degree of Ph.D. Applicants should, therefore, have a good honours degree in physics and some research experience, not necessarily related to the subjects mentioned above. Salary scale: £575 by £25 to £600 per annum. Superannuation under the F.S.S.U. Family allowances.

Forms of application may be obtained from the Registrar, the Manchester College of Science and Technology, Manchester 1, to whom they should be returned not later than September 20, 1958.

CHEMICAL ENGINEERING AND ATOMIC ENERGY RESEARCH

Experimentalists with experience in chemical plant operation and/or chemical engineering research are required to apply chemical engineering techniques to problems involving radioactive substances. H.N.C., or "A" level G.C.E. (including chemistry) or equivalent qualifications (preferably in chemical engineering) are required.

Salary: £420 to £855 or £990 to £1,215 depending on age and experience.

Send postcard to the Group Recruitment Officer (1184/34), U.K.A.E.A., Atomic Energy Research Establishment, Harwell, Didcot, Berks, for application form and details.

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

ST. JOHN'S, NEWFOUNDLAND, CANADA

PHYSICAL CHEMIST

The Memorial University of Newfoundland invites applications from qualified persons to fill the vacant post of Assistant Professor of Chemistry, to teach Physical Chemistry up to honours degree standard. Appointments will be made for an initial period of two years and are renewable. The salary range is $5,400 to $6,000/$6,000 to $6,500/$6,500 to $7,000. Appointments may be made at a salary within the scale depending on the training and experience of the applicant. The person appointed will be eligible to join the comprehensive pension scheme, Medical Plan, and in addition will be assisted in moving to Newfoundland to a maximum of $750.

Applications should be addressed to the President, Memorial University of Newfoundland, St. John's Newfoundland, Canada, in time for appointment by September 15, 1958; two copies of application should also be sent to the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Additional particulars may be obtained from the President.

UNIVERSITY OF SHEFFIELD

Applications are invited for a post of Lecturer or Assistant Lecturer in Physics to begin duties on January 1, 1959, or as soon as possible thereafter. Some experience of X-ray crystallography desirable but not essential. Salary scales: Lecturer, £900 by £50 to £1,350 by £75 to £1,650; Assistant Lecturer, £700 by £50 to £850, with F.S.S.U. provision and family allowance. Initial salary on either scale according to qualifications.

Further particulars may be obtained from the Registrar, to whom applications (four copies) should be sent by September 13, 1958.

DIRECTOR

CAWTHRON INSTITUTE, NELSON, N.Z.

Applications for the above position are invited from those who are academically well qualified, of proven scientific leadership and administrative ability, to develop researches primarily into plant nutrition problems of horticulture and agriculture. Salary scale £2,000 to £2,250.

Details are obtainable from the Managing Secretary, Cawthron Institute Trust Board, Box 29, Nelson, N.Z., or the N.Z. High Commissioner, 415 Strand, London, with either of whom applications close on September 30, 1958.

GHANA PUBLIC SERVICE COMMISSION

Applications are invited for the following vacancy in the Fisheries Department. Fisheries Officer: To assist in the development of marine and freshwater fisheries; to further the use of power-driven fishing vessels and improved methods of fishing; to assist in the introduction of modern methods for the preservation and distribution of fish; to investigate scientific and technical problems relating to the fishing industry. Candidates must (1) possess a degree of a recognized university in natural science; and must be actively interested in natural history; (2) a mechanical aptitude is an advantage; (3) only male candidates are eligible for consideration. Appointment may be on pensionable or contract terms for two tours each of 18-24 months' duration. Salary £680 to £980 per annum plus overseas pay £175 to £275 a year pensionable, and £990 to £1,490 a year (including overseas pay) contract. Gratuity at the rate of £8 6s. 8d./£12 10s. for each completed month of residential service payable on completion of contract. Outfit allowance of £60 on first appointment. Free first-class passages for officer, wife and up to three children under 18 years and in addition an education allowance for children when not resident in Ghana of £100 a child for up to three children under 18 years. Generous home leave on full pay. Income tax at low local rates. Preservation of superannuation or pension rights, where applicable, can be arranged.

For further particulars and application form write, stating age, qualifications and experience, to The Director of Recruitment, Ghana High Commissioner's Office, 13 Belgrave Square, London, S.W.1.

IMPERIAL COLLEGE OF TROPICAL AGRICULTURE

TRINIDAD, T.W.I.

Applications are invited for the post of Bursar at The Imperial College of Tropical Agriculture, Trinidad, West Indies, which will become vacant early in 1959. Applicants should preferably be either qualified accountants or members of the Chartered Institute of Secretaries; or if not they should have had extensive experience of financial administration in an academic institution. The present salary scale is £1,550 by £40 to £1,750 by £50 to £1,900, the point of entry being determined by the successful applicant's qualifications and experience, but salary scales are now under review and a substantial increase is likely. The post is pensionable and carries entitlement to passages and overseas leave for the officer and his family. Unfurnished quarters will be provided at a reasonable rental.

Application forms and further details may be obtained from the Secretary, The Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2. Applications must be submitted not later than October 15, 1958.

UNIVERSITY OF LEEDS

UNITED LEEDS HOSPITALS

DEPARTMENT OF MEDICAL PHYSICS

Applications are invited for the post of Physicist at a salary on the scale £625 by £25 to £700 a year, according to qualifications and experience. Candidates should have an honours degree in physics, but experience in radiation work is not essential. Duties will be concerned with problems of radiation protection and research in related fields. Facilities are available in the department for acquiring experience in the applications of physics to medicine and for preparing for a higher degree.

Applications (three copies), stating date of birth, qualifications and experience, together with the names of three referees, should reach the Registrar, the University, Leeds, 2 (from whom further particulars may be obtained), not later than September 1, 1958.

LABORATORY TECHNICIANS REQUIRED by Northern Rhodesia Government Pneumoconiosis Medical and Research Bureau for one tour of 36 months in first instance with prospect of pensionable employment. Salary scale £745 rising to £1,260 a year. Commencing salary up to £1,080 a year according to experience. Free passages. Liberal leave on full salary. N.H.S. Superannuation rights can be preserved in approved cases. Candidates aged 23 to 40, must possess Inter-I.M.L.T. and have all-round knowledge of laboratory techniques. A particular interest in biochemistry, the bacteriology of tuberculosis and histology and experience in the handling of small animals would be an advantage.—Write to the Crown Agents, 4 Millbank, London, S.W.1. State age, name in block letters, full qualifications and experience and quote M.3C/44725/NF.

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

The Chemistry Department has a vacancy for an Assistant Experimental Officer to help with research work on the composition of milk, milk products, feeding stuffs, etc. Candidates should possess a suitable degree, G.C.E. with chemistry at advanced level, or equivalent qualifications. Previous analytical experience an advantage. Salary scales £370 (at age 18) to £800 (men) or £744 (women) with superannuation.

Apply, with full particulars, to the Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting reference 58/22.

WOOLWICH POLYTECHNIC

LONDON, S.E.18

Applications invited for Research Assistantships in (1) Physics, and (2) Telecommunications from honours graduates. The Assistantships will normally lead to the Ph.D. degree (Internal) of the University of London and are tenable for two to three years. Value £440 to £470 a year.

Particulars and application form from Clerk to Governors.

UNIVERSITY OF LEEDS

DEPARTMENT OF GEOGRAPHY

Applications are invited for appointment as Research Assistant in the Department of Geography at a salary of £400 a year. Candidates should have a good honours degree, a knowledge of German and ability to draw maps. Appointment for one year in the first instance, renewable; the successful candidate may apply for acceptance to study for a higher degree.

Applications (three copies), stating date of birth, qualifications and experience, together with the names of two referees, should reach the Registrar, the University, Leeds, 2 (from whom further particulars may be obtained), not later than September 8, 1958.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Assistant Lecturer in Botany. The salary scale is £700 to £850 per annum. Membership of F.S.S.U. and children's allowance scheme.

Applications should be sent not later than September 30, 1958, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

UNIVERSITY OF MALAYA

SINGAPORE

Applications are invited for (A) Lectureship or (B) Assistant Lectureship in Pathology from candidates with registrable medical qualifications. Salary scales: (A) £1,295 by £49 to £1,442/£1,540 by £56 to £1,988 per annum, (B) £1,148 by £49 to £1,246 per annum, entry point according to qualifications and experience. Allowances: expatriation in range £280 to £308 per annum, cost of living in range £210 to £560 per annum. Passages for appointee, wife and children under 12 years. Part-furnished quarters at reasonable rent. Provident Fund Scheme.

Detailed applications (six copies), naming three referees, by September 30, 1958, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

SCIENCE MUSEUM LIBRARY: RESEARCH Assistants. Two pensionable posts for men or women at least 22 on September 1, 1958, with (normally) University degree in an engineering or science subject and a knowledge of at least two modern foreign languages. Starting salary (men) £550 (at 22) to £685 (at 26 or over). Maximum £850. Promotion prospects.—Write, Civil Service Commission, 30 Old Burlington Street, London, W.1, for application form, quoting S.4884/58. Closing date September 16, 1958.

DEPARTMENT OF SCIENTIFIC AND INdustrial Research. Principal Scientific Officer. Pensionable post for Engineer or Physicist at least 31 on January 1, 1958, at Mechanical Engineering Research Laboratory, East Kilbride, Glasgow, to lead team carrying out research on heat transfer in a new laboratory with exceptional facilities. Qualifications normally first- or second-class honours degree in an appropriate subject or high professional attainment. Sound knowledge of basic principles and experimental techniques of heat transfer and fluid mechanics necessary. Industrial experience desirable. Salary scale (men) £1,370 to £1,950. Good housing prospects.—Write Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, for application form quoting No. S.4881/58. Closing date September 23, 1958.

UNIVERSITY OF CAPE TOWN/ PROVINCIAL ADMINISTRATION OF THE CAPE OF GOOD HOPE/ JOINT MEDICAL STAFF

LECTURER IN ANATOMY

Applications from suitably qualified persons are invited for the post of Lecturer (Grade E) in Anatomy. The appointment will be made under the terms of the Joint Staff Agreement between the University of Cape Town and the Provincial Administration of the Cape of Good Hope. The successful candidate will take part in the theoretical and practical teaching of medical students and of medical auxiliaries. The salary is £1,860 per annum plus a temporary cost of living allowance for a married man (at present £234 per annum).

Applications (with copies of testimonials), should state age, qualifications, experience, publications and research interests and give the names of two referees whom the University may consult. Two copies of the application and testimonials should reach the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (from whom memoranda giving the general conditions of appointment and further information about the work of the department of Anatomy should be obtained), not later than September 30, 1958. An additional copy should be sent direct by airmail to the Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa. The University reserves the right to recommend the appointment of a person other than one of the applicants or else to recommend no appointment.

COLONIAL OFFICE

Applications are invited for three posts of Agronomist with the Colonial Pool of Soil Scientists based on the Macaulay Institute for Soil Research, Aberdeen, for assignment to various Colonial territories to undertake field experimentation following soil survey. Candidates should have a good honours degree in science or in agriculture with botany and chemistry. Field experimentation experience would be an advantage. Salary according to qualifications and experience, in the Scientific Officer (£615 to £1,080) or Senior Scientific Officer (£1,160 to £1,370) National salary scale plus additional allowances when overseas.

Application forms and further information obtainable from Colonial Office, London, S.W.1, quoting RES.308/01.

COVENTRY EDUCATION COMMITTEE

COVENTRY TECHNICAL COLLEGE

Laboratory Steward required for Chemistry and Biology Laboratories. Some knowledge of chemistry and experience of handling scientific apparatus desirable. Wages 4s. 5½d. to 5s. per 44 hour week, plus a working bonus of 11s. All employees expected to belong to appropriate trade union.

Application forms and conditions of appointment from the Director of Education, New Council Offices, Earl Street, Coventry.

UNIVERSITY OF SOUTHAMPTON, ZOOlogy Department. Research Assistant required as from September 1, 1958, to investigate effects of chemical pollutants on marine organisms (under Grant from Atomic Energy Authority). Good degree in chemistry or biochemistry essential. Some research experience or qualification preferable. Maximum salary £600 according to qualifications. —Applications, including names of two referees, to reach the Professor of Zoology not later than September 6, 1958. Further particulars may be obtained from the Secretary and Registrar, University of Southampton.

THE BRITISH SOCIETY FOR RESEARCH in Agricultural Engineering requires Physicists or Engineers in the following departments: Glasshouse (C.1) for design and development of environmental control for plant research purposes. Modern techniques will be used and interest in one or more of the following subjects would be useful, viz., light and radiation, heat transfer, air conditioning, transparent plastics. Instrumentation (Inst. 1) to take part in development of measurement and control equipment for wide range of applications in research and testing. Mechanical Engineering (M.E.1) for research and development in connection with tractors. Candidates must have first- or second-class honours degree and those who have completed degree in 1958 will be considered. Salary scales: As for Scientific Officer or Senior Scientific Officer in Scientific Civil Service, £595 to £1,050 or £1,130 to £1,330. Five-day week, F.S.S.U.—Application forms from Secretary, N.I.A.E., Wrest Park, Silsoe, Beds., quoting above reference numbers.

UNIVERSITY OF TASMANIA

AUSTRALIA

LECTURER IN PSYCHOLOGY

The University invites applications for the above position. The Lecturer will be required to work mainly in the field of experimental psychology but capacity to undertake work in other branches would be an advantage. The salary scales for lecturers are Grade II £A.1,450 by £A.60 to £A.1,630, and Grade I £A.1,630 by £A.60 to £A.2,050. Appointment will be offered within the range for Lecturers Grade II or Grade I according to qualifications and experience. An allowance is made towards travelling expenses and housing assistance is available.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications in Australia and London, is October 31, 1958.

UNIVERSITY OF QUEENSLAND

AUSTRALIA

SENIOR LECTURER IN PHYSIOLOGY (ANIMAL)

Applications are invited for the above position. Applicants should possess a veterinary qualification or a degree in science, and should have research experience in comparative or general physiology preferably with knowledge of and experience with domestic livestock. A biochemical or pharmacological approach to comparative or veterinary physiology would be acceptable. Opportunities exist for investigations involving neuromuscular, endocrine, or environmental (heat and light) physiology. Salary £A.2,160/£A.2,510.

Further particulars and application forms are obtainable from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close, in London and Australia, on October 15, 1958.

VICTORIA UNIVERSITY OF WELLINGTON

NEW ZEALAND

SENIOR LECTURER IN MATHEMATICS

Applications are invited for the above position. The salary will be £1,315 per annum rising by annual increments of £50 to £1.615. The initial salary will be determined according to the qualifications and experience of the appointee. An allowance is made towards travelling expenses.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in New Zealand and London, is October 31, 1958.

UNIVERSITY OF WESTERN AUSTRALIA

CHAIR OF SOIL SCIENCE

Applications are invited for this newly created Chair in the Institute of Agriculture. The salary will be £A.3,500 per annum. An allowance is made towards travelling expenses and housing assistance is available.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close, in Australia and London on October 8, 1958.

D.S.I.R. FIRE RESEARCH STATION, BOREham Wood, Herts, requires Scientific Officer for work on growth and spread of fire and associated combustion and fluid flow problems. Qualifications: first- or second-class honours degree, in physics, chemistry or engineering. Salary range: (men), £595 to £1,050. Allowance for National Service and postgraduate experience. Normal prospects of promotion in mid-thirties to Principal Scientific Officer. (Salary range £1,370 to £1.950.) —Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1 (quote A.312/8A). Closing date September 20, 1958.

JUNIOR TECHNICIAN (PREFERABLY male, age between 15 and 16 years) required for the Department of Zoology, University of Edinburgh.—Applications, stating age, qualifications and experience, to be sent to the Secretary to the University, Old College, South Bridge, Edinburgh, not later than September 1, 1958, quoting Reference Z/JT/8/58.

NOTTINGHAM AND DISTRICT TECHNICAL COLLEGE

BURTON STREET, NOTTINGHAM

Principal: D. A. R. Clark, M.Sc.(Tech.), M.I.Mech.E.

Applications are invited for the full-time appointment of Assistant, Grade B, in General Chemistry. A large new building comes into use in September next for well-equipped Departments of Building and Civil Engineering, Electrical Engineering, Chemistry, Physics and Mathematics, and Mining. Increased accommodation is also available to the Departments of Mechanical Engineering, Arts and Commerce, Printing and Textiles. Research work by both staff and students is being rapidly developed. Experience in industry, teaching and/or research desirable. Salary in accordance with the Burnham Technical Scale as follows: £650 by £25 to £1,025 per annum. Additions include degree allowance of £75 per annum (or £125 for good honours degree), up to three increments of £25 for training in approved cases and incremental allowance for industrial experience after age 21, and war service.

Further particulars and form of application may be obtained from the Principal, to whom completed forms should be returned not later than September 6, 1958.

CENTRAL ELECTRICITY GENERATING BOARD

Require HEALTH PHYSICISTS for Nuclear Power Stations at Bradwell (Essex) and Berkeley (Glos.). Successful candidates will have responsibility for radiological measurements in and around the station to which they are appointed and for personnel safety. Good scientific qualifications are required, preferably of degree standard, and some industrial experience in a responsible position would be an advantage. Specialized knowledge of health physics is not essential as the successful candidates will be given an adequate course of training, expected to begin in November, 1958, and last approximately nine months. Salaries within range £1,560 to £1,665 per annum.

Applications, stating age, qualifications, experience, present position and salary, should be forwarded to I. G. Ellis, Personnel Officer, 24/30 Holborn, London, E.C.1, by September 1. Please mark envelopes "Confidential" and quote ref. N/241.

COMMONWEALTH BUREAU OF HELMINTHOLOGY

THE WHITE HOUSE,
103 ST. PETER'S STREET, ST. ALBANS, HERTS

Scientific Assistant required for work in scientific information service involving abstracting and indexing. Good science degree, reading knowledge of two European languages (preferably other than French or German) and ability to write good English essential. Knowledge of helminthology an advantage. Salary scale £595 to £970 (bar) to £1,330 (bar) to £1,460. Age, qualifications and experience considered when fixing starting salary. Up to two increments for compulsory National Service and two extra increments on completing two years' satisfactory service if aged 32 and under. Superannuation according to F.S.S.U.

Applications, stating age, qualifications and experience, together with names of three referees, should be sent to the Director before September 30, 1958.

UNIVERSITY OF GLASGOW

LECTURESHIP OR ASSISTANTSHIP IN AGRICULTURAL BOTANY

Applications are invited for a Lectureship or Assistantship in Agricultural Botany. Salary scale: Lecturers, £900 to £1,650; Assistants, £700 to £850. Initial salary according to experience and qualifications. F.S.S.U. and family allowance benefits.

Applications (eight copies) should be lodged not later than August 30, 1958, with the undersigned, from whom further particulars may be obtained.

ROBT. T. HUTCHESON,
Secretary of University Court.

RUCHILL HOSPITAL

GLASGOW, N.W.
VIRUS LABORATORY

Honours science graduate required for virus work in tissue culture. Previous experience not essential. Salary on Whitley scale for biochemists and physicists range £625 to £1,000 according to experience.

Applications by September 15 to the Physician Superintendent.

WESTERN REGION OF NIGERIA

DEPARTMENT OF AGRICULTURE
SOIL SCIENTIST (ANALYST)

To carry out soil analyses and nutritional studies of cocoa and annual crops as a member of a team. In addition will probably be required to take over, for limited periods, the general duties of an agricultural chemist. Candidates must have a good honours degree in chemistry (or equivalent) and should have had one or two years suitable postgraduate training or experience. Appointment on contract/gratuity terms with emoluments in scale £1,086 to £1,944 per annum. Gratuity of £37 10s. is payable for each completed period of three months' satisfactory service. Outfit allowance £60. Free passages on appointment and leave for officer, wife and up to three children under 13 years of age. Furnished quarters at moderate rental. Generous leave.

Apply, giving brief particulars, to Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/410/015.

GAMBIA

LIVESTOCK IMPROVEMENT OFFICER

To investigate fodder resources and subsequently initiate a programme of work designed to establish a mixed farming system of agriculture. Candidates must have a university degree in agriculture and considerable knowledge and experience of crop and animal husbandry. Appointment on contract/gratuity terms with salary in scale £1,212 to £1,842 per annum. Gratuity £37 10s. for each completed period of three months' service (including leave). Quarters at low rental. Free return passages for officer, wife and up to two children. Generous leave.

Apply, giving brief particulars, to Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/12/013.

NORTHERN REGION

NIGERIA

Entomologist required in the Veterinary Department of Northern Nigeria. Duties involve tsetse surveys and identification of species; field observation on seasonal distribution and habits of tsetse flies, particularly *Glossina morsitans*; and duties in connection with the control of the species. Candidates must possess a natural science degree from a British university and preferably a knowledge of tsetse, particularly *Glossina morsitans*. Appointment may be (a) on three years probation for permanent and pensionable employment. Pension (non-contributory) at rate of 1/600th of final pensionable emoluments for each completed month of reckonable service. Salary in scale £804 to £1,950 a year; or (b) on short-term contract (two tours each of 18 to 24 months) with salary of £870 to £2,118, and gratuity (taxable) of £37 10s. for each completed period of three months service (including leave). Starting salary in both cases depends on qualifications and experience. Quarters provided at low rental. Taxes at local rates. Annual leave permissible; generous home leave granted after each tour. Free passages in both directions for officer and wife; assisted passages for children. Allowances for children of £120 a year for first child, £96 for second and £72 for third.

Application forms from Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.67/408/015.

BRISTOL EDUCATION COMMITTEE

COLLEGE OF TECHNOLOGY
SCHOOL OF PHARMACY
ASSISTANT LECTURER, GRADE B, IN PHARMACEUTICAL SUBJECTS

Governors invite applications for this full-time post, vacant September 1, 1959. Candidates should have degree in pharmacy or pharmaceutical qualification. Teaching, research or industrial experience an advantage but not essential, and recent successful entrants to final examinations now having postgraduate training may apply. Burnham Technical Scale salary: men, £650 by £25 to £1,025; women, £580 by £20 to £820, plus equal pay increments. Additions for degree and training and where applicable increments for approved industrial experience.

Details and application forms from Registrar, College of Technology, Bristol, 7.

MEDICAL RESEARCH COUNCIL REQUIRE a Senior Technician at the Department of Experimental Medicine, Cambridge. General physiological and biochemical laboratory experience essential. Salary on scale £620 to £760 or £660 to £840 per annum. Four weeks' annual leave. Superannuation provision.—Write, giving full particulars, to the Director, Department of Experimental Medicine, 5 Shaftesbury Road, Cambridge.

SENIOR EXPERIMENTAL OFFICER

and

EXPERIMENTAL OFFICER

required by

THE ATOMIC WEAPONS RESEARCH ESTABLISHMENT, ALDERMASTON, BERKS.

Post 1 (Ref. 1963/34)

The post carries responsibility for the construction of high energy condenser banks designed to produce very heavy current gas discharges. Duties include development and construction of the banks, design of high voltage low inductance switching systems, development of oscillographic methods of measuring the performance of the banks and supervision of technical staff.

Pass degree, H.N.C., or equivalent qualification required. Familiarity with high voltage laboratory techniques and pulse circuitry essential. Candidates should be at least 35 years of age.

Salary: £1,360 to £1,630 per annum.

Post 2 (Ref. 1990/34)

To assist in experimental work designed to assess the hazards of handling high explosives. Duties will include development work on dust extraction equipment. Applicants, who should be at least 26 years of age, must be prepared to travel to Outstations and to work in the open.

H.N.C. in appropriate subject required, but applicants with H.S.C. or G.C.E. in five subjects including English language at "O" level, and two scientific or mathematical subjects at "A" level, will also be considered.

Some experience of handling high explosives would be desirable, and experience of dust control methods or machine shop practice would be an advantage.

An ability to design and construct experimental apparatus is required.

Salary: £990 to £1,215 per annum.

Contributory Superannuation Scheme. A house, or assistance towards legal expenses on house purchase, will become available for married officers living beyond daily travelling distance.

Postcards for application forms to the Senior Recruitment Officer at above address. Please quote appropriate reference number.

ADEN

FISHERIES OFFICER

To organize and develop the domestic fisheries of the Colony and Protectorate. Candidates, male, must have a university degree in Natural Science (Zoology) and preferably some experience of fishery administration. Appointment on probation to the permanent establishment with pensionable emoluments in range £1,032 to £1,929 per annum, or on contract/gratuity terms. Gratuity at the rate of £25 to £37 10s. for each completed period of three months' service. Free passages on appointment and leave for officer, wife and up to four children. Furnished quarters normally available at moderate rental. Outfit allowance on first appointment.

Apply, giving brief particulars, to Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/2/01.

MID-ESSEX TECHNICAL COLLEGE AND SCHOOL OF ART

MARKET ROAD, CHELMSFORD

Required as soon as possible, Laboratory Technician. Preference will be given to candidates who are qualified as Instrument-makers or Physics Technicians. Duties include supervision of work of Science Laboratory Staff. Salary: Grade IV for Miscellaneous Classes of Officers: £565 by £20 to £625.

Further particulars and forms of application from the Clerk to the Governors.

MEDICAL LABORATORY TECHNICIAN. Vacancy will occur end of August. Qualified A.I.M.L.T., science degree or equivalent. Whitley conditions.—Apply, in writing, to Administrative Officer, North London Blood Transfusion Centre, Deansbrook Road, Edgware, Middlesex.

UNIVERSITY OF OTAGO
DUNEDIN, NEW ZEALAND
SENIOR LECTURER OR LECTURER IN MATHEMATICS

Applications are invited for this position. Salary range: Senior Lecturer, £1,315 by £50 to £1,615 per annum; Lecturer, £1,025 by £50 to £1,275 per annum.

Further particulars are available from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close in London and New Zealand on September 30, 1958.

RESEARCH FELLOWSHIPS IN GOVERNMENT Scientific Establishments: Senior and Junior Research Fellowships, tenable for three years, in a very wide range of subjects. Qualifications: normally first- or second-class honours degree and evidence of a very high standard of ability in research. At least two years' postgraduate experience expected for Junior Fellowships (three years for Senior Fellowships). Rates £1,100 to £1,350 for Senior Fellowships and £750 to £1,000 for Junior Fellowships. F.S.S.U. applies.—Write Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, for application form, quoting S.4798/58.

NATIONAL PHYSICAL LABORATORY, Teddington, Middlesex, has vacancies in Applied Physics, Basic Physics, Light, Mathematics, Metallurgy, and Standards Divisions. Qualifications: first- or second-class honours degree or equivalent in appropriate subject. Postgraduate research experience an advantage. Posts unestablished with possibility of establishment whilst under age 31. Salary: Scientific Officer, £635 to £1,110. Senior Scientific Officer, £1,190 to £1,410 (men). Women slightly less.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. No. A.135/8A.

APPOINTMENTS VACANT

THE BRITISH DRUG HOUSES LTD., HAVE a vacancy in the Chemical Research Department for a young graduate interested in heterocyclic chemistry. Previous experience of research desirable but not essential. Conditions of employment are good. There is a superannuation fund (contributory) and the Company operates life assurance and profit-sharing schemes.—Write, stating age, qualifications, experience and salary required, to Personnel Manager (Ref. VP), The British Drug Houses Ltd., Graham Street, London, N.1.

WANTED. CUSTODIAN (PART-TIME) FOR small Nature Sanctuary, North Essex coast. No qualifications necessary but must have keen interest in natural history (general or specific) and some knowledge of small craft and outboards. Free cottage. No remuneration.—Write Box Z.R.848, Deacons Advertising, 36 Leadenhall Street, E.C.3.

METAL BOX COMPANY LIMITED

has vacancies for

GRADUATE PHYSICISTS

in Research Laboratories, Acton (West London). Interesting and original work concerned with development of instruments and automatic inspection devices. Good class degree required and some specialized knowledge of technical optics or electronics desirable. Permanent posts, and superannuation. Appropriate experience will be recognized in salary, rising from £700 per annum.

Write, Staff Division,
The Metal Box Company Ltd.,
37 Baker Street, W.1,
quoting Ref. REP/21.

BRITISH TITAN PRODUCTS COMPANY LIMITED

has a vacancy for

AN INORGANIC/PHYSICAL CHEMIST

in its Research Department at Billingham, Co. Durham

Applications are invited from first- or second-class honours degree graduates. It is desirable but not essential that they should have had several years' industrial experience in the pigment, paint or allied industries. Alternatively, they should have been working on problems involving surface chemistry or polymer formation or degradation reactions.

Salary and prospects are very attractive for a man with the right qualities; conditions of work are good: a Staff Bonus, Superannuation Scheme and non-contributory Life Assurance are in operation; housing assistance is available if required.

Applications will be treated in the strictest confidence and should be addressed to the Personnel Manager, British Titan Products Company Limited, Billingham, Co. Durham, quoting S.1.

THE WELLCOME FOUNDATION LIMITED require a graduate chemist (B.Sc. or A.R.I.C.) with drive and initiative, for a post as Production Chemist at the Wellcome Chemical Works, Dartford, Kent. The work entails supervision of the manufacture of pharmaceutical chemicals and may also include the direction of laboratory investigations into process improvement. Previous manufacturing experience, whilst an advantage, is not essential.—Applications should be sent to the Personnel Manager, Wellcome Chemical Works, Dartford, Kent.

QUALIFIED CHEMIST IS REQUIRED BY an expanding Group handling and processing animal by-products. Duties comprise analysis and the control of the quality of products, as well as the acquiring of a current knowledge of technical developments in the animal by-products processes. The successful candidate will have an honours degree in chemistry and will have a sound grasp of bacteriology. In addition he should have some years' industrial experience with a commercial organization. Salary according to qualifications. This is definitely a progressive position with good prospects.—Apply Box 700, T. G. Scott and Son, Ltd., 1 Clement's Inn, London, W.C.2.

IMPERIAL CHEMICAL INDUSTRIES Limited has a vacancy in its Pharmaceuticals Division Research Laboratories at Alderley Park, Alderley Edge, Cheshire, for a senior Experimental Biologist. The appointment is concerned, in the first instance, with the chemotherapy of parasitic nematodes. Research experience is essential and candidates should be under 35 years of age.—Applications, with full particulars, should be addressed to the Staff Manager, Imperial Chemical Industries Limited, Pharmaceuticals Division, Fulshaw Hall, Wilmslow, Cheshire.

SPILLERS LIMITED REQUIRE FOR THEIR Animal Nutrition Research Laboratories at Middle Aston, Oxford, a graduate, preferably with a Ph.D. and aged about 30 to undertake experiments on the nutrition of farm animals; preference will be given to persons with some experience in the animal feed compounding industry.—Please send applications to Dr. J. L. Williams, Spillers Limited, Animal Nutrition Research Laboratory, Middle Aston, Oxford.

TECHNICAL LIBRARY AND INFORMATION Bureau requires a male Assistant preferably 21 to 35 years with knowledge of chemistry and physics, French and German. Some acquaintance with biology useful. Good prospects. Five-day week. Staff restaurant and bonus scheme.—Please apply to the Personnel Officer, Griffin and George Ltd., Ealing Road, Alperton, Middlesex.

THE MILK MARKETING BOARD WILL shortly appoint an Experimental Officer to be responsible for the handling and freezing of bull semen at the Board's Deep Freeze Unit at Northampton. Applicants must have a good knowledge of general laboratory technique and experience in the research field is also desirable. The commencing salary will depend on age, qualifications and experience.—Applications, giving full personal details, should be sent to Personnel Officer, Milk Marketing Board, Thames Ditton, Surrey.

HOSIERY AND ALLIED TRADES RESEARCH ASSOCIATION
HEAD OF DEVELOPMENT DEPARTMENT

Applications are invited from Graduates with a good physics degree for the above post which will shortly become vacant. Commencing salary in the range £1,050 to £1,350, according to qualifications and experience. Superannuation benefits under the Federated Superannuation System for Universities.

Further details may be obtained from the Secretary, Thorneywood, Gregory Boulevard, Nottingham, to whom applications should be sent within fourteen days of the appearance of this advertisement.

GRADUATE WITH DEGREE IN BOTANY, or diploma from recognized training college, wanted for work on nutrition and maintenance of fungi for pure culture. Exciting field with good salary and prospects.—Write Box No. 703, T. G. Scott and Son, Ltd., 1 Clement's Inn, London, W.C.2.

RESEARCH CHEMIST. MUREX LIMITED, Rainham, Essex, require graduate chemist with industrial experience to assist Leader on research and development work (not analytical) on the extraction of the rarer metals. The work is interesting and offers good prospects. Excellent working facilities. Contributory superannuation scheme.—Write, giving age, experience, etc., to Staff Department.

TECHNICAL INFORMATION OFFICER, male or female, required by Edwards High Vacuum Limited, Manor Royal, Crawley, Sussex, to take charge of a Library with a staff of four. Applicants (aged 30 to 40 years) should have at least Inter.B.Sc., be able to translate from German and preferably other languages and have held a senior position in an industrial library for not less than three years. Housing available if from London area. Pension and bonus schemes are operated.—Write, giving full details of previous experience and present salary, to the Personnel Manager.

ORGANIC CHEMIST REQUIRED TO TAKE charge of Laboratory engaged in the preparation and development of organic fine chemicals. Practical experience in preparative organic chemistry essential. West London area.—Full particulars to Box No. 702, T. G. Scott and Son, Ltd., 1 Clement's Inn, London, W.C.2.

A YOUNG PHYSICAL CHEMIST OF PH.D. standing is required to carry out fundamental research on problems connected with the colloid chemistry of starch. An initial salary of £1,000 per annum is envisaged, with participation in the Federated Superannuation System for Universities.—Applications, together with the names of two referees, should be sent to the Director of Research, British Baking Industries Research Association, Chorleywood, Hertfordshire, by September 29, 1958.

PFIZER LTD.

Pharmaceutical and Chemical Manufacturers with a rapidly expanding factory at Sandwich have a vacancy for a

Microbiologist

with experience in Vitamin and Antibiotic Assays.

This post offers the successful applicant a progressive position with excellent prospects of promotion.

The Company operates a non-contributory Pension and Life Assurance scheme. Initial removal expenses will be paid.

Applications, giving fullest details regarding previous experience, qualifications, age, etc., should be made to

PERSONNEL OFFICER,
PFIZER LTD.,
137-139 SANDGATE ROAD.
FOLKESTONE.
quoting ref. F.6706.

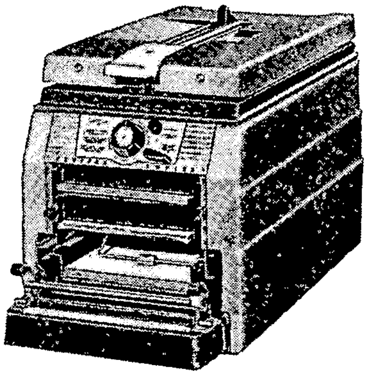
THE LANGUAGE OF PHYSICS is full of difficulties for the transcriber. It has a profusion of symbols, italics, superior signs and inferior figures. It annexes names and descriptions from many languages. It defeats the keyboard and confuses the typist.

But it cannot defeat the 'Verifax' Copier. Being based on a photographic process, the 'Verifax' Copier will transcribe everything on the original, whether it is printed, typed, handwritten or drawn. It is speedy, too — will give you three dry copies, ready for use, in less than a minute. It is compact, self-contained, and takes up little more desk space than a typewriter. Let us send you full details.

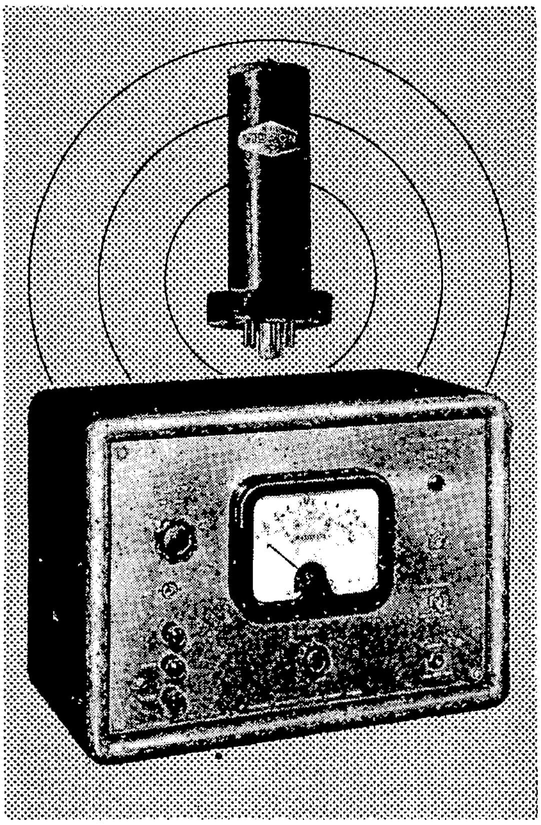


Particularly suitable for research departments and laboratories where written or printed material is often difficult to copy.

KODAK Verifax COPIER

Kodak Limited, Dept. 478, Kodak House, Kingsway, London, W.C.2

'Verifax' is a registered trade-mark



E·I·L

The VIBRON

is a new electronic component, which replaces the electrometer valve in the measurement of very small currents.

The VIBRON is a vibrating condenser unit which, in a suitable circuit, can measure currents as small as 10^{-14} ampere, or resistances as high as 10^{15} ohms, to an accuracy of ±2% and with a zero stability of ±100 microvolts in twenty-four hours. It can be supplied as a unit for building into instruments of your own design, or, alternatively, VIBRON instruments of several types are available from E.I.L.: the Model 33B Electrometer shown here is an example.

Manufactured under British Patent No. 550610 and Patent Application No. 35637/54.

SCIENCE, BUSINESS AND EDUCATION

TWENTY-SIX years ago, the papers read to the Department of Industrial Co-operation (a group within Section F) at the centenary meeting of the British Association were published under the title "Business and Science". The main emphasis in these papers is on management, but a glance at their titles in the context of automation and other subsequent developments shows the prescience of the organizers of that gathering. Sir Alexander Fleck borrows the title of the volume for his presidential address at the Glasgow meeting of the Association (see p. 573 of this issue of *Nature*). To some it may appear that his address is platitudinous; but the charge is unjustified. Some familiar truths are indeed re-stated, but there are others, notably in regard to the nature of business activity, which badly needed to be re-stated and are more often disregarded than put into effect.

Sir Alexander, however, adds to his title the words "A Balanced Partnership", and in doing so displays the quality that gives his address its distinctive character and value. Disclaiming any intimate acquaintance with the practice of particular disciplines, he speaks, much as the late Lord Stamp spoke at Blackpool, as one who, himself trained as a scientist and understanding the framework within which scientific thought develops, is also familiar with the outlook and problems which confront the business or industrial administrator who is concerned to make generally available the services or goods which scientific and technical knowledge can provide. In that connexion it is pertinent to recall that, when last November the Prime Minister announced his choice of Sir Alexander Fleck to preside over the three committees of inquiry into the accident at Windscale, Mr. Macmillan gave as the decisive reason his belief that in the highly technical aspects of the accident Sir Alexander had sufficient scientific knowledge of a general character.

Whatever so-called platitudes this address may contain, they are re-stated with the clarity to be expected of one whose recognition of the importance of clear exposition and vivid interpretation is well known, and with the balance and perspective which are often derived from the simultaneous study of science and history which once again Sir Alexander advocates in this address. But above all they are emphasized by the wealth of experience and the sound judgment which have frequently marked Sir Alexander as pre-eminently the man to fill some particular post where understanding of both science and public affairs is required.

This note of authority sufficiently refutes any real thought of platitude; but there is a further reason which gives particular interest to a presidential address quite distinct from those of most of his predecessors. In itself, it demonstrates the decisive importance of both a balanced outlook and a balanced education in order to achieve that partnership of science and business which Sir Alexander regards as fundamental, and especially a balanced relation between science and government which is no less essential. As Sir Alexander observes, if science is to further our social evolution, it needs the financial and productive effort of business, while no less fundamentally, the prosperity of Great Britain depends on the technologically sophisticated products of our export trade.

Sir Alexander devotes about half his address to indicating how this balanced partnership between science and business can be achieved; but his suggestions are concentrated mainly on the place of the scientist in the business structure and on the achievement of balance in education. What Sir Alexander says about the functions of the scientist in business indeed leads up to and underlines the necessity for balance in education, for the avoidance of premature specialization, the formation of character and the development of intellect and personality. He recognizes indeed that education must to some extent aim at providing useful members of society, and he does not believe that to do so—even in the universities—is completely contrary to the British tradition of individual liberty. But while in framing our formal education we cannot entirely ignore the requirements of the society in which that educational system exists, he points out that that society will not be tolerable to live in if its members are not permitted to develop their personalities and talents.

This respect for the desires and personality of the individual also pervades Sir Alexander's brief survey of the functions and opportunities of the scientist in business. He stresses the importance of research and illustrates the way it functions, the dependence upon team-work between specialists in varied scientific disciplines, the distinction between research and development and the functions of design and construction. All this is set forth with lucidity and authority; but Sir Alexander is no less emphatic and convincing in showing how the scientific mind has its essential part to play in production and in the commercial departments, as well as at the level of management and higher administration. Moreover, that contribution cannot be rendered without flexibility and adaptability of mind, as well as breadth of experience. While it is to be hoped that due note will be taken in the appropriate quarters of the importance of scientists infiltrating almost the whole business structure, so that at every administrative level there are those competent to assess for themselves technological or scientific advice, it is no less desirable that scientists themselves should appreciate what Sir Alexander says about the way in which they can fit themselves for high responsibility.

The balance we seek must come in large measure, in Sir Alexander's view, from within the individual himself, derived from the education which the scientist and the non-scientist should receive. Once again he stresses the need for those who study the humanities to have some understanding of the workings of science, and for the scientist to be able to relate his science to its human context both historically and in terms of the present day. Ultimately, it is on this process that Sir Alexander relies to ensure that full use is made of the scientist in business, both by giving his powers full scope and by fitting him for wider responsibilities and more varied duties.

On that note, that a truly balanced partnership of science and business will manifest itself in the growing use of science and its methods in business, and that such a partnership can only come from a balanced education for scientists and business-men alike—with the reminder that the society which such a partnership can help to build will always require courage, integrity and tenacity—Sir Alexander closes. He himself would be the first to disclaim any novelty for his ideas. In one form or another they have been repeatedly urged in the post-war period, though never with greater cogency. We may well be grateful that they have again been set forth so lucidly from the presidential chair of the British Association by one who speaks with the authority and experience which Sir Alexander can command.

Nor need we be pessimistic as to their effect. It is more than twenty years since the late Lord Stamp, also in a presidential address to the British Association, examined the impact of science upon society and, touching on cultural lags in a dynamic society, approached this question of balance at a different angle. Lord Stamp's address displayed the same sense of responsibility on the part of business as does Sir Alexander's, but he said little or nothing about the vital question of education, and his remarks about the scientific worker in a wider field lacked the incisiveness of Sir Alexander's. In the interval, the question of education has come to the front, and there are few things more encouraging than the growing recognition, especially in the past few years, of the vital importance of a balanced education. We have still to reach agreement as to the way or ways in which such an education can be provided, though some notable leads have been given in recent months. Sir Alexander's address will bring a new sense of urgency and inspire the co-operation and understanding that are essential for the sustained effort which he himself recognizes as the true line of advance.

SIR GEOFFREY TAYLOR'S WORK ON THE MECHANICS OF SOLIDS

The Scientific Papers of Sir Geoffrey Ingram Taylor
Edited by Dr. G. K. Batchelor. Vol. 1: Mechanics of Solids. Pp. x+593. (Cambridge: At the University Press, 1958.) 75*s*. net.

IT was an excellent idea to publish in collected form the scientific papers of Sir Geoffrey Taylor, papers which have done so much to establish our modern views on the mechanics of real materials. When Sir Geoffrey began his researches about forty-five years ago the only serious attempt that then existed to understand the mechanical properties of matter in terms of atomic structure was the kinetic theory of gases; and this theory could say scarcely anything about the turbulent motion which is man's oldest and most familiar experience of the mechanics of gases. Practically nothing was understood about solids and liquids. Apart from a few theorems on the elasticity of crystals, both these states of matter were discussed by analogy with hypothetical continuous media which had certain ideal properties. The laws of these media owed nothing to the particulate structure of matter, and the things they predicted were often so different from what occurred in real materials that the subject was no longer regarded as physics but applied mathematics. Even within the framework of these idealized laws, many problems remained unsolved. Turbulent flow, for example, was scarcely less difficult for the theory of ideal liquids than for the kinetic theory of gases. As for calculating the viscosity of water from first principles, or understanding why a piece of copper wire stretches a certain amount and then breaks at a certain stress when pulled at its ends, such things were quite out of question. This part of the subject seemed so unapproachable that at least one distinguished scientist ventured the opinion "ignorabimus" about it.

Although it deals only with solids—the papers on fluids are to appear in three other volumes—this first volume of Sir Geoffrey's papers shows most fascinatingly how the science of the mechanical properties of matter has become transformed over the past forty years and how this transformation has been brought about mainly by these papers themselves. The first three papers, published jointly with A. A. Griffith in 1917–18, describe the famous method for solving problems of torsion in elasticity by the use of soap films, whereas the last paper, which was read in Madrid at a conference in 1955, contrasts plastic slip in body-centred cubic and face-centred cubic crystals, and develops from this contrast a theory of why polycrystalline iron differs from metals such as aluminium and copper in its plastic properties. What a striking development of the subject this represents! Here one is dealing with plastic slip in real crystals, taking full account of the crystal structure and its influence on the slip process, distinguishing between one metal and another, and at the same time taking full account of the polycrystalline structure of the material and the effects of intercrystalline boundaries.

The forty or so papers that have made this possible are all set out in this volume, and they include several that were written originally for Government departments or advisory committees and are published here for the first time. Those familiar with the subject will enjoy being reminded of all the branches that were pioneered by Sir Geoffrey's work; for example, the early papers with Miss Elam that established the crystallographic laws of slip in metals; the papers on stored energy in cold-worked metals; the famous paper written in 1934 on dislocations, the theory of which was foreshadowed in another of Sir Geoffrey's papers published by the Faraday Society in 1928; the paper in 1938 which showed for the first time how to deal mathematically with the plastic deformation of polycrystalline aggregates; the papers on plastic waves and effects of shock loading; and the papers on the laws of plastic deformation under combined stresses. Those new to the subject will find in these papers an introduction which, for originality, clarity, enjoyment, enthusiasm, and authority, could not be better. The editor of this volume, Dr. G. K. Batchelor, and its sponsors, the Ministry of Supply and Trinity College, Cambridge, are to be congratulated on their valuable enterprise. A. H. COTTRELL

NUCLEAR PHYSICS AND ATOM BOMBS

Brighter Than a Thousand Suns

The Moral and Political History of the Atomic Scientists. By Dr. Robert Jungk. Translated into English by James Cleugh. Pp. 350. (London: Victor Gollancz, Ltd., in association with Rupert Hart-Davis, Ltd., 1958.) 21*s.* net.

DR. ROBERT JUNGK attempts in this book to write "The Moral and Political History of the Atomic Scientists" or "the inside story behind the construction of the atomic and hydrogen bombs". The story is written largely around personalities, including Rutherford, Bohr, Heisenberg, Joliot-Curie, Kapitza, Fermi, Oppenheimer, Szilard and Teller. The author has obtained his knowledge at second hand by diligent inquiry from a galaxy of scientists whose help is acknowledged in the introduction.

The story opens with Rutherford's disintegration of nitrogen by α-particles and rapidly switches to Göttingen to describe the life of the scientific notables of the day—Born, Frank, Klein, Heisenberg and Hilbert, with their numerous visitors, including Bohr, Blackett, Dirac, Oppenheimer and Pauli. It describes the dismissal of the seven Jewish professors from Göttingen, including Max Born and Courant, after Hitler's seizure of power, and follows this with a sympathetic account of Niels Bohr's Institute of Theoretical Physics in Copenhagen, referring to his "Castle of Carlsberg" and an amusing parody of Faust in which Bohr and Pauli were principal characters.

From here the story turns to Cambridge, where a highly inaccurate account of the Cavendish Laboratory is given. The nuclear physicists, including Blackett, Oliphant, Feather and myself, are said to have worked as a kind of "subordinate section" directed by Kapitza. He refers also to Kapitza's "baby giants of high voltage". Nothing could be farther from the truth, for Kapitza took no part in experimental nuclear physics at this time. Kapitza's detention in the U.S.S.R. in 1934 is said to have had "a disruptive effect on the Cavendish as a whole" and "Rutherford's own mighty frame suddenly began to age". This again is more fiction than fact.

The narrative then moves to Rome and Fermi's work on the production of radioactivity by neutrons. The author discusses why fission was not discovered in these experiments, and suggests that physicists did not appreciate that neutrons might be able to penetrate the potential barrier of heavy elements. Since Fermi was producing radioactivity in many heavy elements this is nonsense. What the physicists and chemists failed for so long to realize was that processes other than the emission of protons, α-particles and electrons could take place. There is also an account of supposed friction between Madame Joliot and Madame Meitner resulting from the Solvay Conference of 1933. The discussions are reported verbatim in the Solvay Conference Papers and do not support this. These early chapters do not therefore provide high marks for the author's credibility or scientific knowledge.

After this the story goes on to the discovery of fission and thereafter to the war years and the 'uranium project' in Germany, which was directed entirely to producing a heavy water atomic pile and never to produce an atomic bomb. The narrator gives an account of discussions between Houtermans and Weizäcker in 1941, in which he states that the two agreed that the first and most important task of uranium policy must be to keep departments in the dark about the now imminent feasibility of manufacturing such bombs. The author's general thesis about the German atomic energy project is contrary to the conclusions of Goudsmit in "Alsos".

After this the story moves to the United States, to describe the origin of the atomic project in that country and the development of the Manhattan project, and then devotes two chapters to Oppenheimer's founding of Los Alamos and the development of the atomic bomb.

The author then gives an account of the discussions as to whether and how the atomic bomb should be used and describes the labours of the United States 'Interim Committee' which had to advise the President on this question. The Interim Committee had a scientific panel consisting of Oppenheimer, Fermi, A. H. Compton and E. O. Lawrence. These discussions have been described in much more detail and from first-hand knowledge in A. H. Compton's book "An Atomic Quest". Opinion on the scientific panel was divided as to whether and how the bomb should be used. There were similarly divided views among the staffs of the Chicago laboratories. However, the doubts of the scientists produced little effect, and Mr. Stimson, Secretary for War, has given his own account of the reasons, based on potential loss of American lives, which led him to advise that the bomb should be used. Dr. Jungk records General Grove's view that President Truman did "not so much say yes as not say no".

The story moves on to the years of McCarthyism in the United States and the investigation of Robert Oppenheimer. It retells the now familiar story of the debates as to whether the United States should develop the hydrogen bomb.

One chapter of the book is devoted to the Fuchs case. The author makes the remarkable and ridiculous suggestion that the Russians might have denounced Fuchs to the British Intelligence Service to upset Anglo-American relations.

The author concludes that these events have forced physicists to leave their 'ivory towers' and to be made aware of their responsibilities to the world.

The book as a whole is interesting, but it cannot be considered as an accurate historical account of these developments. JOHN COCKCROFT

CO-OPERATIVE PHENOMENA

Changes of State

A Mathematical-Physical Assessment. By H. N. V. Temperley. Pp. xi+324. (London: Cleaver-Hume Press, Ltd., 1956.) 50*s.* net.

THE term 'changes of state' would usually be taken to imply primarily the processes of fusion and evaporation for which, typically, the transition temperature is sharply defined. There are, however, many other changes of state which proceed more gradually as the temperature changes; and a 'critical temperature' may be associated not with a latent heat but with, for example, a discontinuity in the specific heat. "Until comparatively recent times", the author says, "the underlying similarities of all changes of state have not been realised". In this volume, he directs attention to the formal similarities, and discusses fully the individual peculiarities. After a short historical introduction, he classifies the various types of change from a thermodynamic point of view, gives a general account of basic theoretical considerations, and then surveys in detail the main fields in which changes of state are involved. Successive chapters deal with evaporation, fusion, solutions and order–disorder phenomena, ferromagnetism and antiferromagnetism, ferroelectricity, superconductivity, and the transition of liquid helium.

The author deals mainly with the development of interpretative descriptions of collective behaviour, using justifiable or plausible 'models', that is, essentially, assumed types of interaction between atoms or molecules. He is not usually concerned with precise comparisons with experiment, for the models which can be fully worked out are so idealized that, he says, "the emergence of a theoretical curve passing through the experimental points is not *quite* the occasion for rejoicing that it is in other branches of physics". The book is thus essentially theoretical. It is not heavily mathematical in form, except for occasional outbursts, but a clear understanding of the often complex mathematics involved underlies many of the accounts given in words of the theoretical treatments.

Only a small part of the book deals directly with changes of state, either generally or specifically. Indeed, once an atomic and statistical mechanical treatment is embarked upon, the theory of changes of state cannot be isolated from the theory of the characteristics of the 'phases' between which transitions occur. The main bulk of the book consists of concentrated surveys of some of the most difficult, complex, and controversial problems of theoretical physics arising in the treatment of such co-operative phenomena as those of ferromagnetism and superconductivity.

It is impossible in a short review to do justice to the author's vast range of reading, to his penetrating critical powers, and to the care he has taken in incorporating in a personal assessment a balanced survey of the complementary, or sometimes contradictory, theoretical treatments which have been given of the various phenomena. There are few readers who will not find on almost every page some novel and thought-provoking comment or suggestion.

In spite of the author's own clear-headedness, and the lucidity of his exposition of so many difficult pieces of theory, the book makes very formidable demands on the reader. Most of the chapters are in effect concentrated monographs, but they are not sufficiently independent for separate reading. For a proper appreciation of one of these chapters the reader must have in mind not only the opening chapters of the book but also sections embedded in other earlier chapters and often in later ones, too. Above all, however, bearing in mind that this is a book intended "to help actual and potential research workers to 'find their way around' this fascinating but complicated field", the main issues tend to be confused by the packing in of details which could be fitly accommodated only in specialized treatises of more restricted range.

It may be that the book has just grown from a consideration of changes of state, but after the event a more informative title might have been devised, perhaps including the words 'co-operative phenomena'. The field is almost coterminous with that of the physics of matter, and is of immense importance. There is no other single account of the theoretical aspects as comprehensive as that given here. The journey through the book is difficult, but it is to be hoped that many will face its ardours; they will be richly rewarded. E. C. STONER

RUSSIAN ASTROPHYSICS

Theoretical Astrophysics

Edited by V. A. Ambartsumyan. Translated from the Russian by J. B. Sykes. Pp. xii + 645. (London: Pergamon Press, Ltd., 1958.) 135*s*.

THIS book is a translation of a well-known Russian text-book, a co-operative work by five authors, E. R. Mustel, V. V. Sobolev, A. B. Severnyi, S. B. Pikel'ner, and V. A. Ambartsumyan, who also acted as general editor. The Russian version appeared in 1952 and few corrections or additions have been made for this English edition, although an editorial preface rather ruefully comments on the difficulties created by the very rapid development of astrophysics in recent years.

The reader will find a thorough treatment of those parts of the subject which were the centre of attention between the Wars, but little on other branches which have grown so spectacularly during the past ten or fifteen years. The development of new photometric methods and of radio astronomy, and the application of electronic computers to the internal structure of stars, have led recently to a concentration on problems of galactic structure, of interstellar matter, of star populations and stellar evolution, and have also revived interest in the older techniques of astrometry, radial velocities, etc. Little of these subjects appears here. This is understandable enough and scarcely a cause for complaint, but I would have preferred the book to have had a less general title, giving a more precise indication of the contents. A comprehensive account of theoretical astrophysics is to-day beyond the powers of one author and beyond the capacity of any ordinary text-book, while rapid growth and change make early obsolescence almost inevitable. These are very real and serious difficulties, in whatever language the book may be written.

Sixteen chapters, about half the book, are devoted to the problems of stellar atmospheres, especially the theory of radiative equilibrium, the formation of continuous spectra, Fraunhofer lines, etc. There are six informative chapters on the outer layers of the Sun, including a welcome introduction to the electrodynamic problems which are to-day of such great importance. There are three chapters on planetary nebulæ, two on novæ, and two on stars with bright-line spectra. There are three brief chapters dealing with the internal constitution of stars, confined mainly to the earlier, classical theory. There are also two chapters on the scattering of light in planetary atmospheres and two on interstellar matter.

The book is slightly more elementary than Unsöld's "Theorie der Sternatmosphären". It is a welcome addition to the comparatively few general texts of solid worth which are now available, and Western readers will find it interesting, too, as an indication of the method of approach adopted for Russian students. Although there are differences of detail, on the whole the treatment is very similar to what would be expected in any good work from Western Europe or the United States. There is a natural tendency to refer to Russian authors in preference to others. In some ways this is a healthy check to Western complacency, but there are some slightly surprising omissions. For example, Hertzsprung does not appear in the index and the cinematography of prominences is discussed without Lyot.

The translation appears to be good and there are few misprints. R. O. REDMAN

ADVANCE OF CHEMICAL TECHNOLOGY

Encyclopedia of Chemical Technology

Edited by Raymond E. Kirk and Donald F. Othmer. First Supplement Volume. Pp. xvii+974. (New York: Interscience Encyclopedia, Inc., 1957. Distributed by Interscience Publishers, Inc.; London: Interscience Publishers, Ltd.) 25 dollars.

IT is more than ten years since the first volume of Kirk and Othmer's "Encyclopedia of Chemical Technology" appeared. Volume 15, which appeared in 1956, brought the alphabet to its end. That volume was reviewed in *Nature* (179, 983, 1957). I expressed satisfaction then that it had been decided to issue a supplementary volume, because an encyclopædia 'however beautiful is ephemeral', unless it can be maintained up to date by some means or other. The purpose of this Supplementary Volume of 974 pages is to bring the Encyclopedia up to date. As pointed out in the foreword, obsolescence is most uneven. Some of the articles in the earlier volumes needed to be brought up to date by alluding to minor improvements in production methods or by providing more up-to-date statistics, but in other articles changes of method may have been so great that considerable revision was indicated. In preparing the Supplementary Volume, the principle adopted has been to describe fully those bigger changes, rather than to make minor additions to the many different articles. Some articles have been added on subjects which were not treated in detail or not at all in the original volume; for example, fluidization and automation.

There are fifty-one articles in the Supplementary Volume, arranged alphabetically. Cross references are made to the original volumes as well as to this one. The index of 43 pages covers the Supplementary Volume alone, and should be consulted together with the very complete index to the original fifteen volumes which formed the greater part of Volume 15.

It is noticed that this new volume is called the First Supplement Volume, and it is well that the publishers seem to be allowing for the future and that further volumes may be expected which will maintain the current utility of the Encyclopedia. Many of the separate articles state at the outset the reasons which have led to their inclusion in the Volume and their relation to former articles in the Encyclopedia and some of the articles give at the end, in a few sentences, the main conclusions and expectation of further progress. This procedure is helpful to the user of this or subsequent supplementary volumes of the Encyclopedia.

The original purpose of Kirk and Othmer's Encyclopedia was to produce a "comprehensive treatment of the American Chemical Industry". The joint authors were successful. Raymond E. Kirk, the senior editor, died after a short illness early in 1957; he lived to see the completion of his great work. The Supplementary Volume opens with a tribute to his memory by his collaborator, Donald F. Othmer.

Glancing through the volume, the first article deals with "Acrolein" and its derivatives, in which the condensation products leading to new polymers are described. "Adhesives" provides the next subject, dealt with in a general way showing the advances made since the preparation of the article in the first volume, particularly in metal-bonding. An interesting article follows on "Algal Culture". Utilization efficiency in growing *Chlorella* is only between 2 to 8 per cent, because of the low light-saturation point. Yields of 20–40 tons an acre a year could be reasonably expected on the basis of the present technology, but there are difficulties attending most of the schemes which have been tried. The articles on "Computers", describing and listing their various types, give a great amount of assistance in the choice of suitable equipment for the study of problems in chemical engineering. "Cyanoethylation", in which the proprionitrile group is involved, forms the subject of the next article, which discusses the recent important development of cyanoethylated cotton, along with polyacrylonitrile fibres. There is considerable reference to "Detergents" in the Encyclopedia, and the new section on this subject brings information up to date. There is no reference in this article to the difficulty of effluent treatment caused by the use of detergents. "Emulsion paints" are referred to as a major development in the paint industry. The binder in water paints is glue or casein, which is made soluble in the water; in emulsion paints, it is insoluble and dispersed in very fine droplets.

"Industrial Enzymes", like papain, are used for chill-proofing of beer, for making meat more tender and for pharmaceutical purposes. 'Pectic' enzymes are used widely in the fruit juice industry. A table is given of industrial and food enzyme preparations on p. 309. "Epoxy resins", derived from epichlorohydrin, have found in recent years many applications as durable crosslinked polymers, used for protective coatings, finishes, metal-to-metal adhesives and structural materials.

Modern methods of "Extraction" as a chemical engineering unit operation are considered in a special article—an unusual example is cited, namely the extraction of fission products of spent nuclear reactor fuel by using molten silver, cerium or lanthanum as selected solvents. "Fluidisation" is one of the chief articles and it is a particularly useful addition to the Encyclopedia. On p. 399 is a diagram representing the results of a number of investigations on heat transfer between fluid beds and tube walls.

The supplementary article on "Hydrocarbon Oxidation" deals with vapour phase oxidation of the lower saturated aliphatic hydrocarbons and outlines, in not too dogmatic a manner, the theory of the chain reactions which can take place. In practice, formaldehyde, methanol, acetaldehyde and acetone are the main commercial products in the oxidation of propane and butane, which is carried out at 100–300 p.s.i.g., sometimes using oxygenated air. "Ion Exchange Resins" are becoming applied for many different purposes. The article refers to water treatment, to recovery of uranium from low-grade ores, to recovery of gold and other metals from cyanide leach, and to processing various pharmaceutical products.

The article on "Peracetic Acid" is excellent. Not many years back, peracetic acid was just a dangerous substance; now, though still unstable when pure, it has become (in solvents or formed *in situ*) an important oxidizing agent for epoxidation of natural oils and their derivatives, and a number of other uses. An article on "Photovoltaic Solar Converters" describes the advances made in photovoltaic cells for the direct conversion of the energy of light to electrical energy, using silicon or cadmium sulphide; other substances, such as gallium arsenide, indium phosphide or cadmium telluride, should be effective.

Polymerization of pure isoprene in the presence of a lithium metal catalyst produces a polymer with structure substantially identical with that of natural rubber. This and other developments in artificial rubber production are presented in the article on "Rubber". "Sorbic acid", a fungistatic agent for foods, has an article to itself, in which methods of production and other uses are described. "Steroids with Corticle Hormone Activity", describing the constitution and production of cortisone and derivatives, provides a valuable review and literature summary, including the cortexone derivative.

This Supplementary Volume contains articles of great current interest which illustrate the remarkable rate of progress of technology.

An encyclopædia is not only valuable for reference and for obtaining knowledge about some special subject, but, like a library, it is pleasant to browse within it, for browsing as well as study often leads to new ideas. This supplementary volume of "Kirk and Othmer" maintains the excellent standard of presentation of the main series of volumes and is an essential addition to the set. A. C. Egerton

EMULSIONS

Emulsions

Theory and Practice. By Paul Becher. (American Chemical Society Monograph Series, No. 135.) Pp. ix+382. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1957.) 100*s*.

One of the most complex of the systems dealt with in colloid science is that of the emulsions. This is in no small measure due to the fact that they are essentially metastable and in disequilibrium. Dr. Becher quite rightly introduces the subject by giving a brief review of the properties of interfaces and the characteristics of surface activity. In this section the author covers a lot of ground; the discussions on solubilization and on micelle structures are particularly welcome, although the treatment of Gibbs's fundamental equation and its experimental verification might have been dealt with in greater detail, especially in its applicability to micelle-forming electrolytes.

The general physical properties of emulsions are next described before attempting to inquire into the theoretical basis for the apparent stability of such systems as well as the cause of phase inversion. These chapters are excellent in that they emphasize the importance of the interfacial phase in acting as a barrier to the coalescence of liquid drops when brought in contact with one another. Not only must the electrostatic component of the repulsive forces which is approximately proportional to ζ^2, where ζ is the electrokinetic potential, as well as the London, or van der Waals, forces, be considered, but also there is increasing evidence that in the aqueous phase at least the water in close proximity to the interphase has become more ice-like under the influence of the potential gradient existing there, and that the breaking of this ice-like layer in the act of coalescence is a factor that cannot be left out in any computation.

The author rightly points out that the phenomenon of coalescence is an important initial step in both phase inversion and in creaming, where the emulsion separates into two phases, one rich and one poor, in the disperse phase, and the views of Cockbain and of Schulman are clearly presented.

The next two chapters are devoted to a classification of the different types of emulsifying agents and to the various techniques which have been developed for the preparation of emulsions.

The variety of surface-active agents employed for emulsion formation is now extremely extensive. In general, the chemical constitution of such amphipathic substances effects a nice balance between the polar and non-polar portions of the molecule which may be positively, negatively or zero charged. Some discussion on this balance would not have been out of place in this section; for example, a consideration of the ratio of the number of ethylene oxide groups to methylene groups required for a good aliphatic non-ionic detergent. There are two appendixes, one on testing and the other on commercial emulsifying agents.

This is a well-written book, concise in the American style, and the theoretical treatments, where developed, are integrated more closely in the corpus of the volume than is usual in such books. There are few obvious misprints. The format and printing are well up to the standard that we have come to expect of the American Chemical Society Monographs.

Eric K. Rideal

CHEMISTRY OF PLANTS

The Chemistry of Plants

By Prof. Erston V. Miller. Pp. vii+174. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1957.) 38*s*. net.

The principal function of a book on the chemistry of plants is to provide a source of information on the composition of plant tissues and the chemical properties of their major constituents. For the majority of readers, however, such a book would be made more interesting by some discussion of the metabolic relationships of these constituents. In his preface Prof. Miller makes it clear that he does not embrace this latter view and has specifically avoided encroaching on the domain of the plant physiologist.

In fact, the author has not been entirely successful in this and does offer a certain amount of biochemical information, but in quality and amount this is insufficient to redeem the failings of the book as a source of factual information. The author describes himself as "a mere compiler", but in this book he has rather been a collector of the compilations of others. All the tables, except one, are borrowed from other texts, and in most cases this transfer has reduced their value in that they were not specifically designed for their present context. This has the effect of making the presentation scrappy and the density of information variable and in many places very low. For example, there are given very few quantitative data on the composition of plant tissues and no information on the composition of plant proteins, though both types of data are readily available.

In view of this latter criticism, one might hope that the qualitative data be satisfactorily presented, but unfortunately, this is not the case, as its chemical content is particularly open to criticism. Many substances are mentioned without any indication of their structure being given, other substances of quite elementary importance, such as the unsaturated fatty acids, are inadequately described and some of the information given is quite inaccurate. Isocitric acid is not "the D-isomer of citric acid", hæmocyanin is not, so far as we know, closely related to chlorophyll, and phosphorylases are not to be confused with phosphorylating enzymes. These are just a small sample of the many errors which suggest that the author would be more at home in some other field than the chemical one. Finally, the price is rather high for a book of this size and the text would have to be very greatly improved to justify it.

G. Leaf

CELLULAR BIOLOGY

Les Facteurs de la Croissance Cellulaire

Activation et Inhibition. Publiés sous la direction de Prof. J. André Thomas. (Exposés Actuels de Biologie Cellulaire : 2è série, 1956.) Pp. xii+428+3 planches. (Paris : Masson et Cie., 1956.) 4,000 francs.

A GREAT many books and reviews on the biology of the cell have been produced in recent years, and since the War many new techniques have been applied to this field of research with startling success. Here is yet another review, and although many of the topics dealt with have been more widely surveyed in recent years, often by the same authors, this new collection of articles is nevertheless valuable. With ten authors involved in the production of nine chapters there is inevitably some unevenness in quality. On one hand, some authors have notably failed to include references to all the major work in their field, while on the other an outstanding contribution with a most comprehensive bibliography is that of Chouard and Thimann, who discuss "Les facteurs de la croissance cellulaire végétale".

The reviews included range from the synthesis of proteins through growth in animal and plant cells, growth and differentiation in embryos, the inhibition of mitotic activity, wounding and grafting, to a final review of cancerous growth. Brachet's paper, entitled "Les facteurs d'activation et d'inhibition de la synthèse des protéines", forms an excellent introduction to this subject, and could be read with great advantage by final-year honours students. This can also be said of the chapter by Chouard and Thimann mentioned above. The other contributions are less likely to have a general appeal. In particular, it is remarkable that in a book of this nature there should be no chapter dealing with the great advances which have recently been made in our understanding of the normal physiology of cell division. Instead there are two chapters on "Les facteurs de la mito-inhibition" (Deysson and Dustin), and one on "Les facteurs de la cytonarcose" (Gavaudan), and, although all are interesting, they deal primarily with the toxicology and pharmacology of mitosis.

The final two chapters, on wounding and grafting (May) and on cancer (Oberling), are both interesting, but they are too brief to be of any great value. Indeed the whole book is of an introductory nature, and, apart from the serious omission mentioned above and the pharmacological over-emphasis, its greatest value will be to provide an outsider with some knowledge of modern research work on cellular biology.

W. S. Bullough

A FARMER'S GUIDE TO ANIMAL DISEASES

Veterinary Guide for Farmers

By G. W. Stamm. Edited by Dallas S. Burch. Third edition. Pp. 384. (Chicago, Ill.: Windsor Press, 1957.) 3.95 dollars.

ANIMAL diseases are of great importance to all farmers, for upon their incidence can depend the success or failure of the enterprise. A reduction in the losses caused by animal diseases would greatly benefit the farming community, and the aim of this book is to assist farmers to accomplish this by providing them with information on the diseases which can affect their stock.

The book has been written clearly and concisely, and much technical veterinary knowledge has been simplified and expressed in a manner which can be understood by practical farmers. The book is well produced and excellent photographs and informative diagrams make the author's meaning clear. As the book was written for American farmers it deals with poisonous plants, parasites and diseases which are unknown in the British Isles, and advises the use of drugs, such as antibiotics, which cannot be purchased by farmers in these islands. Also, in dealing with some diseases, no mention is made of prophylactic preparations which British farmers are using extensively. However, providing the reader has the knowledge to appreciate which sections are applicable to his particular conditions, he can obtain information about the diseases which can affect his stock, and the measures which can be adopted to prevent their spread.

This book, however, aims at taking the farmer further than the elementary principles of first aid and the important aspects of disease prevention, and provides information which will enable him to diagnose and treat disease. Skill in diagnosis is an art which can only be acquired by long experience, and text-book knowledge can, in certain cases, increase losses by leading to an inaccurate diagnosis and faulty treatment. An additional point is that veterinary surgeons are relying increasingly on diagnostic aids such as bacterial examinations and biochemical analyses which are not available to farmers. Other sections of the book dealing, for example, with the diagnosis of pregnancy, do not stress the time and practice needed to acquire skill in the technique.

The book is an excellent one of its kind and contains much valuable information, and, in the foreword, the author warns his readers not to take chances with sick animals, but to seek veterinary advice in cases of uncertainty; but it does tend to encourage farmers to perform for themselves services which would be more efficiently provided by the veterinary profession.

J. O. L. King

D'ARCY WENTWORTH THOMPSON

D'Arcy Wentworth Thompson

The Scholar-Naturalist, 1860–1948. By Ruth D'Arcy Thompson. Pp. xi+244+8 plates. (London: Oxford University Press, 1958.) 25*s*. net.

All of us who knew D'Arcy Thompson personally and the many who made his acquaintance through the pages of "Growth and Form" have reason for gratitude to his eldest daughter for this finely written biography. It brings vividly into memory that majestic figure and ponderous, admirably phrased utterance. There has been, as all must agree, no one like him in the world of zoology, or possibly in that of any other science, in our time.

He outlived his contemporaries, and most of us who knew him first met him as the author of "Growth and Form" and professor of natural history at St. Andrews, already on the high plateau of the last half of a professorial career that was to extend over sixty-four years. Of how many people would one remember the very first words heard from them? But there is vivid recollection of the opening phrase in an address he delivered before the Royal Physical Society of Edinburgh some thirty-five years ago. Speaking of Johannes Schmidt and his then recent discovery of the breeding places of the eel, he began, "Aristotle"—a long pause and then again—"Aristotle, who knew a little about everything but not everything about anything . . ." and we were launched on an account of modern achievement against a background of classical knowledge.

But, as we learn with so much interest from this 'life', the journey up to the summit of achievement and recognition had been full of disappointments. The chair at Dundee, obtained at the age of twenty-four, was after all a poor alternative to the fellowship at Trinity, Cambridge, that he had hoped for, and there were repeated failures to obtain other chairs or museum directorships. No comparative anatomist, he was out of step with his contemporaries and had he died before the publication of "Growth and Form" (when he was already fifty-seven) he would have had scant attention in any subsequent history of zoology.

His achievements to that date lay primarily in the fields of classical scholarship and of fisheries statistics. Even the two visits to the North Pacific as the United Kingdom representative on the Bering Sea Commission in 1896 and 1897, description of which forms perhaps the most interesting chapter in this book, brought him governmental rather than scientific recognition.

All changed in 1917 after the publication of "Growth and Form", and fame was assured. In this remarkable book his wide knowledge, his mathematical ability and, above all, the wide philosophical outlook which he shared with the Greeks whom he studied and so much admired, find full scope. Supremely well written, it has had a major influence on the direction of biological thought and research, the latter the more surprising because its author was not himself an experimentalist. In a postscript to this biography, Prof. P. B. Medawar contributes a critical essay of high distinction on "Growth and Form".

Perhaps the only criticism concerns the illustrations which could, one feels, have been better chosen. But taken all in all, this is a biography not unworthy of its subject and one that should be widely read and the more treasured as time passes, and with it the memory slowly fades of a great zoologist and a most remarkable personality.

ALEXANDRE COLLIN—A PIONEER IN SOIL MECHANICS

Landslides in Clays

By Alexandre Collin, 1846. Translated by W. R. Schriever, with the assistance of J. P. Carrière, R. F. Legget, and D. H. MacDonald; with a Memoir on Alexandre Collin by A. W. Skempton. Pp. xxxvi+160+21 plates. (Toronto: University of Toronto Press; London: Oxford University Press, 1956.) 52*s*. net.

A reference which appears in all the standard soil mechanics text-books is to Alexandre Collin's "Recherches Expérimentales sur les Glissements Spontanés des Terrains Argileux" (Carilian-Goeury, Paris, 1846). It is a work that has been more quoted than read, and the translation by W. R. Schriever, entitled "Landslides in Clay", is most welcome, for the full text of this work, which is of great historic interest, can now be read by a wide public.

Historically, the work is important to civil engineers, for Collin was much ahead of his time; indeed, nothing approaching the quality of his work was done in soil mechanics for another fifty years. He used the inductive approach, carefully measuring up landslides when they occurred and basing his theories on the considerable amount of field evidence which he had collected. These data are still of value. Others of his contemporaries were deriving mathematical formulæ which bore little relation to the soil to which they were applied.

The analysis of slope stability as carried out to-day is fundamentally that outlined by Collin. He did not, however, attach great importance to this analysis and it is relegated to an appendix in the book.

His description of how he measured the mechanical properties of clay is also very interesting. He demonstrated how clay swells and shrinks with a change in water content, and showed how the shearing resistance also changes. This he measured by applying loads to specimens 4 cm. × 4 cm. in section, producing a double shear failure.

It is difficult to understand why this research was not followed up, and in a memoir on Collin, published with the translation, Prof. A. W. Skempton provides some reasons for it. The memoir is helpful, for it evaluates Collin's work not only in its contemporary setting but also shows where it lies in terms of our present-day knowledge.

Translating such a work cannot have been easy, but the English is extremely readable while yet retaining the feel of a work written in French more than one hundred years ago. To read it is a delightful and instructive recreation.

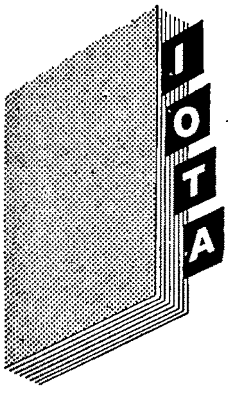
600 journals . . . *read each month!*

Impossible for one man ? . . . a routine achievement for Iota. Every issue of every technical journal published in Britain is read by the Iota panel of experts. Articles are annotated, classified and listed in the monthly **'Index of Technical Articles.'** Iota can put any article from the Index right onto a subscriber's desk. Journal back issues, or photocopies, are always available. No fuss, no bother. Iota eliminates that growing in-tray of journals . . . makes *your* professional reading much more selective.

Take out *your own* subscription to Iota.
It's only 8 guineas for 12 issues.
Write for specimen copy of the Index.



Don't miss a thing . . . subscribe to ***IOTA***

10^{-8} mm. Hg can be attained on industrial work

From the early days of Vacuum processing, great strides have been made to improve these techniques ; much progress and development of oil diffusion pumps have been accomplished within recent years. Constant demands from industry necessitate still further improvements. Leybold foresaw such future requirements, and started research and development work in this field of vacuum processing many years ago. They have now produced oil diffusion pumps capable of pumping speeds of 30 to 20,000 litres per second, and attaining ultimate pressures of the order of 10^{-5} mm. Hg.

For further information regarding this equipment, please send your enquiries to Leybold Vacuum Sales Ltd., Dept. N.P.

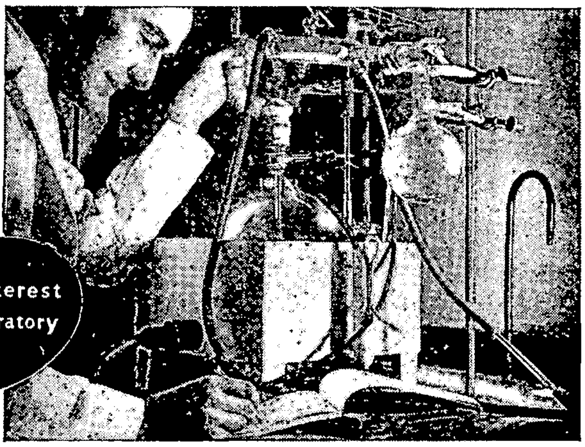
items of interest from our laboratory notebooks



The unique properties of Toluene-3 : 4-dithiol have drawn attention to the potentialities of dithiols in the analytical field. Now comes **Quinoxaline—2 : 3—dithiol** as a quantitative reagent for nickel at the 0.03 to 3.0 p.p.m. level. (**Anal. Chem.**, 1958, **30**, 365) and for the detection of Ni in qualitative analysis (R. E. D. Clark, **Analyst**, in the press). This is all very recent work but the reagent is ready (H. & W. Code 7393).

We have added so many metal indicators (for EDTA titrations) to our range since the last edition of our catalogue that we hesitate to pick on any one for special mention. The most recent was **Naphthyl Azoxine** (H. & W. Code 5959) for Cd, Co, Cu, Pb, Ni and rare earths (see **Anal. Chem.**, 1957, **29**, 821), but we have most others already in stock.

Nitrosoresorcinol monomethyl ether is a comparatively new colorimetric reagent for iron and cobalt. There are others, of course, but S.M. Peach (**Analyst**, 1956, **81**, 371) considers that this one has some particular advantages. For instance, the Co complex can be extracted into an organic solvent. The reagent will appear as an addition (H. & W. Code 6303) in our next catalogue amendment.

Health Yearbook, 1956

Compiled by Prof. Oliver E. Byrd. Pp. vi+278. (Stanford, California: Stanford University Press; London: Oxford University Press, 1957.) 40*s*. net.

Since 1943 the University of Stanford has published an annual Health Yearbook. Over the past few years these have been compiled by Prof. O. E. Byrd, professor of health education, who has brought to his task both diligence and zeal removed from the ordinary. For the 1956 Yearbook Byrd read some 2,000 articles culled from more than 300 health journals. From these he has chosen 254 which constitute a representative sample of the published health literature for 1956. The essence of each article has been patiently distilled and then set down by Byrd in language which would commend it to health educationists, both lay and professional.

The topics discussed include problems of rehabilitation, physical fitness, mental health, heredity and eugenics, infection and immunity, chronic and degenerative disorders, habit-forming substances, dental health, and safety, as well as the facilities available through health authorities, occupational and community health services. There is also a chapter giving accounts of developments in the international health education field, particular attention being paid to Western Germany, South America, Puerto Rico, India, the Soviet Union and Central Africa.

Although most of the book will be of most value to American readers, the editor has chosen his articles so wisely that a large part of it will be of interest and value to health educationists everywhere. Even in matters concerned with the United States, Prof. Byrd has risen above the parochial to set out general principles of health education rather than its local application. Inevitably there is over-lapping and some of the topics appear to hold most interest for the original authors. Yet it is surprising in a compilation of this kind how much of general interest the editor has brought together in a work which will be of value to all those looking for a résumé of important developments in health education during recent years.

K. M. Hawkins

Commonwealth Universities Yearbook, 1958

Pp. xxvii+1337. (London: Association of Universities of the British Commonwealth, 1958.) 84*s*.

The expansion in both size and numbers of the universities of the United Kingdom and of the British Commonwealth has led over the years to a corresponding growth in the Universities Yearbook, which had evolved into a squat bulky volume; the last edition contained more than 2,000 pages. Now the 1958 edition of this valuable work of reference has been issued in a new and much improved format comprising some 1,300 pages of larger size, set in a clearer type from which the subject headings stand out boldly. It is bound between dark blue, dirt-resistant covers. The contents of the book have also been completely rearranged. Hitherto, the United Kingdom has always come first, but now the Commonwealth countries are taken in alphabetical order, headed by Australia, Canada, Ceylon and Ghana. The United Kingdom comes near the end after Uganda, and followed only by the West Indies and an appendix on certain universities—in the Republic of Ireland and the Sudan—having close historical ties with the Commonwealth.

Another distinctive and particularly valuable feature of the new edition is a series of authoritative essays by distinguished academic writers, introducing the sections dealing with Australia, Canada, India, South Africa and the United Kingdom, and describing the system of education in each of these countries leading up to the several university institutions. These essays deal with the history, constitution, relations with the government, and finance of the universities in the countries to which they relate, with sections on pre-university education, conditions of admission and the courses available. Together they form an exceptionally valuable survey of the diverse educational and university systems obtaining in various parts of the Commonwealth.

The directories of the individual universities retain most of the features which have characterized previous editions. They give details of the staffs, activities, regulations and histories of each up to May or June 1957 and in some cases to a rather later date. There is also an appendix giving a statistical analysis of the 10,433 students from overseas enrolled at universities in Great Britain for the academic year 1956–57, and an index of nearly 40,000 names, including all university teachers and administrative officers mentioned in the text.

The Association of Universities of the British Commonwealth is to be congratulated on the changes, which still further enhance the value of this distinguished compendium of basic information indispensable to educationists and to all who are concerned with academic matters.

Bergey's Manual of Determinative Bacteriology

By Prof. Robert S. Breed, Prof. E. G. D. Murray and Nathan R. Smith. Seventh edition. Pp. xviii+1095. (London: Baillière, Tindall and Cox, Ltd., 1957.) 120*s*.

The Bergey Manual is unique among books on bacteriology and a new edition can only be compared with earlier ones. The seventh has been greatly improved by the deletion of material, chiefly of interest to the nomenclaturist, which is to appear in a companion volume, the "Index Bergeyana".

The Manual has a twofold task: to give details of the cultural characters of well-defined species, and to indicate how these species may be collected together into genera and higher ranks. Success in the first depends on the individual authors (there are about a hundred of them) responsible for the particular sections. The new edition is better than the last because many more specialists are included among these authors, and the editorial board has concentrated more on general policy than on writing individual sections. Some of the larger sections, for example the family Enterobacteriaceae, would have been better co-ordinated if they had been written by a group of workers or by the appropriate international taxonomic subcommittee.

As a guide to taxonomic thought the Manual has generally been in advance of similar thought on the eastern side of the Atlantic. In the new edition the thought is still there but it is conventional, and does not seem to be aware that many bacteriologists now question the applicability of a hierarchical system to the classification of bacteria. There is an implicit acceptance of the species concept, and the taxonomic precepts put forward are not likely to be accepted by those whose ideas and thoughts go beyond the immediate identification of the organism. S. T. Cowan

FURTHER STUDIES ON THE PROCESS OF SONG LEARNING IN THE CHAFFINCH (*FRINGILLA COELEBS GENGLERI*)

By Dr. W. H. THORPE, F.R.S.

Madingley Field Station of the Department of Zoology, University of Cambridge

THE songs and other vocalizations of birds are of theoretical interest to both zoologists and psychologists. This is so because, first, they act as social communication systems and as a means of expression—in other words, as a language. Secondly, they provide specific recognition marks which suggest important problems in ecology and evolution. Thirdly, they pose problems concerning the inheritance and genetical control of extremely elaborate behaviour patterns. Finally, the vocalizations of birds can be regarded as offering particularly crucial problems concerning the acquisition of complex behaviour patterns as a result of individual learning.

In an article in *Nature* four years ago[1], it was shown that the normal song of the chaffinch (*Fringilla coelebs*) is an elaborate integration of inborn and learned components, the former constituting the basis for the latter. The present report summarizes very briefly progress which has been made since then. The full account of all the experiments will appear shortly[2].

A good example of a normal song of *F. c. gengleri* is given in Fig. 1. The inborn component of the chaffinch song can be revealed by hand-rearing the young birds from the early nestling life either in acoustic isolation or at least out of contact with all chaffinch song. Six birds thus individually isolated produced songs of an extremely simple type (Figs. 2–4) consisting of a song burst of approximately the correct length (2–2·5 sec.) made up of about the right number of notes. The pitch, or fundamental frequency, of these notes was somewhat lower than normal, and the songs produced by these isolates lacked the division into the three phrases so characteristic of the normal chaffinch song. Moreover, the final flourish and all the other fine details by which the chaffinch song is normally recognized as such were also absent. Of all the hundreds of wild and aviary-kept birds which have passed through our hands during the course of these experiments, none has produced songs of such extreme simplicity as these six birds, although such undeveloped songs are known to occur in the wild at times.

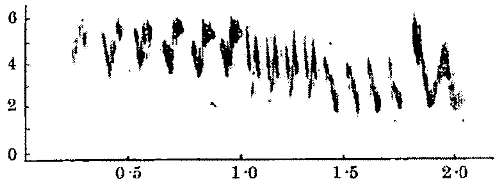

Fig. 1. 'Normal' song of British chaffinch (*Fringilla coelebs gengleri*) *BW/P*, May 9, 1952. Vertical scale: frequency in kc./s. Horizontal scale: time in sec. (Similarly in Figs. 2-11)

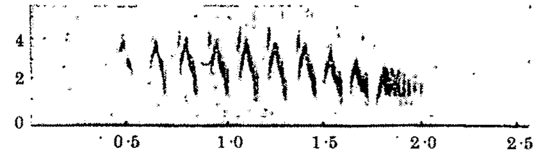

Fig. 2

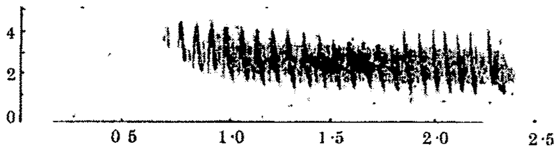

Fig. 3

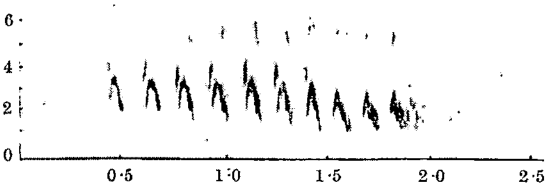

Fig. 4

Figs. 2–4. Song of three hand-reared auditory isolates. *GW*, June 24, 1954; *B/BkY*, May 25, 1957; and *BkW/W*, June 24, 1955

In contrast to the simple, restricted song produced by the isolated birds, we find that if, after babyhood, two or more such birds are put together in a room but still without the opportunity of hearing experienced chaffinches, they will develop more complex songs. It seems that the attempt to sing in company produces mutual stimulation which encourages the development of complexity. The members of each group of hand-reared birds thus kept together will, by mutual stimulation, build up a distinctive community pattern. The birds conform so closely to this pattern that it is sometimes barely possible to distinguish the songs one from another even by electronic analysis. The song of such birds may be quite as complex as that of a normal wild chaffinch, but its complexity tends to be of a different kind and a song thus produced may bear little resemblance to the characteristic utterances of the species. From further experiment it is clear that in the wild, young chaffinches learn some features of the song from their male parents or from other adults during the first few weeks of life. But most of the finer details of the song are learned by the young bird when, in its first breeding season, it first comes to sing in competition with neighbouring territory-holders. There is little doubt that this is the way in which local song dialects are built up and perpetuated. In addition to this true song, the chaffinch, like many other species, has what has been called a sub-song, which is a much quieter and less aggressive affair than is the full song. It is, however, not merely a song of low intensity: it is of an entirely different pattern from the true song and may be described as a long succession of chirps and rattles[2-4]. It seems to have no communicatory function and is most frequently heard in the early spring, when it is produced, so far as we know, much more by first-year birds than by older ones—the latter seeming to come into full song with much less of this preliminary sub-song. There seems little doubt, however, that the sub-song provides in some degree the raw material out of which, by practice and by the elimination of unwanted extremes of frequency, the full song is 'crystallized'. The chaffinch has, of course, like other species, a number of call notes which are in the main signals for co-ordinating the behaviour of the flock, mate and family; some of these may be used as components of both sub-song and full song. It is interesting that call notes are much more in evidence as components of the songs of isolated birds than they are in the songs of normal ones. This is presumably because the isolated birds have had a greatly restricted auditory experience to draw upon as compared with normal wild individuals.

Chaffinches are not imitative birds, in that they do not normally copy anything but sounds of chaffinch origin. Once a chaffinch has heard a chaffinch song as a young bird in the wild, it appears to have learned enough about it to refuse to copy any sound pattern which departs far from the normal; that is, it will learn only the finer individual variations of the song of other chaffinches. So, in the wild, chaffinches practically never, in their full songs, imitate anything but other chaffinches. Hand-reared, isolated birds will learn songs of far greater abnormality, however, provided always that the tonal quality is not too different from that of a chaffinch song. Voices as 'abnormal' as that of a domesticated canary (*Serinus c. canarius*) may be learned by hand-reared birds[3], and very occasionally by wild birds; but when this happens the alien notes are kept as components of the non-communicative sub-song only; the full song is not contaminated with them.

If one catches wild chaffinches in their first autumn and keeps them until the following spring with other chaffinches the song of which is already fixed, one gets clear evidence that the young birds have modelled their songs, in some respects at least, on those of their associates, which have probably come into song first as the spring season comes on, and which they thus hear before they themselves have got very far along the path of song production. Similarly if, instead of exposing such wild-caught first-year birds to the songs of other chaffinches, one plays such songs to them by means of the repeating tape machine which we call a 'song tutor', a clear positive effect is manifest. An experiment carried out in 1954–55 with four wild-caught birds given such tuition in the winter (January 6–20) and with three birds similarly treated in February–March showed clearly the effect of the 'song tutor', there being correct articulation of the phrases and a good approximation in pitch and quality, although there were abnormalities in length and emphasis. If, however, under these conditions one exposes the young birds to highly abnormal songs, no result is obtained. Thus in experiments in 1955–56 such birds were given tuition with a reversed chaffinch song during March. The fact that no definite effect was obtained suggested that enough of the song had already been learned in the autumn for the reversed song to be ineffective even with visually isolated birds. In 1956–57 a similar experiment was done using six wild-caught autumn males and exposing them, in this case not to a reversed song, which was thought to be perhaps too abnormal, but instead to three different 're-articulated' songs (these are songs in which the position of the three phrases has been interchanged). In this experiment the birds were isolated in a soundproof room. Two birds had exposures in September and October, repeated in January, two had exposures in mid- to late-October and late January and early February, and two were similarly exposed in November and February. On the whole, this experiment also had little effect, confirming the tests with the reversed song and suggesting even more strongly that the natural training which the bird has already received by the time it has reached its first winter moult has equally been sufficient to prevent it from learning afterwards the rather large abnormalities characteristic of these re-articulated songs.

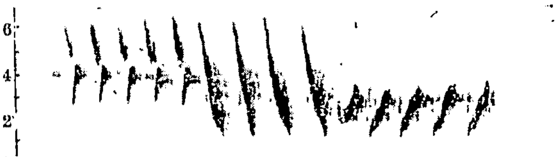

Fig. 5

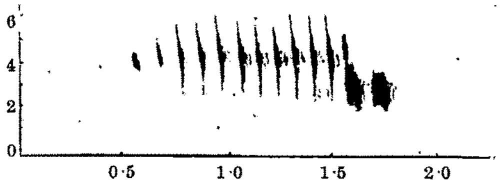

Fig. 6

Figs. 5 and 6. Two songs of a hand-reared auditory isolate after having been exposed to normal song on the 'song tutor' for 10 days only during November of its first year. *GY/BW*, April 24, 1956

When we come to similar experiments with hand-reared birds, very different results are obtained. It was found that a hand-reared visual isolate can be taught features of a normal song from the tape by being exposed to it during November only of its first winter for a period of 10 days. Figs. 5 and 6 give the two songs developed in 1956 by such a bird treated in 1955. The first song shows clearly the influence of the 'tutor', in that it has three phrases otherwise unknown in a hand-reared isolate, having a clear stepwise descent but no end phrase. The second song is of the isolate type plus two end-notes. These experiments thus produce evidence that tutoring, even for a short period in November, can effect the same kind of result as the normal song experience of a wild bird in the field during the autumn. Similar positive results were obtained in similar experiments with re-articulated songs carried out in 1956–57 and 1957–58. Figs. 7 and 8 show such a re-articulated model and its effect on the song of a hand-reared isolate. Hand-reared birds show similar differences from the wild-caught ones, in that if given a reversed song a considerable amount of copying is achieved. Similar experiments with other birds provide further evidence for a previous conclusion that although a hand-reared isolate is incapable by itself of producing anything approximating to a normal ending, yet if once it hears a normal end-flourish on the 'song tutor' (even though in the re-articulated song on the tape it occurs at the beginning or in the middle of the song) it will recognize it as appropriate for an ending and will attempt to place it properly in its own song.

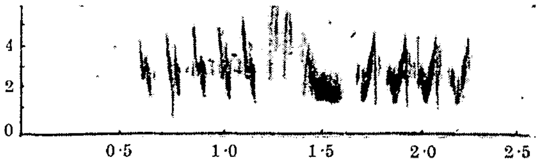

Fig. 7

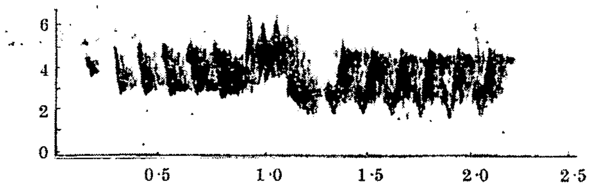

Fig. 8

Fig. 7. Re-articulated model with 'end in middle'

Fig. 8. Song of hand-reared auditory isolate *B/BkP* after having been exposed to this model for 12 days January–February and 12 days February–March. March 25, 1958

In experiments in 1954–55 an attempt was made to indoctrinate hand-reared isolate chaffinches with the song of the tree pipit (*Anthus trivialis*) (Fig. 9), this being chosen because the spectrograph reveals that the tonal quality of the notes is similar to that of the chaffinch. The first experiment gave a doubtful result; but a repeat in 1956 resulted (Fig. 10) in the achievement of a remarkably good copy by such a chaffinch of the song of a tree pipit, resulting in a chaffinch song entirely unlike any other produced in my experience by a wild or hand-reared bird. It is of interest to note that the rather long song of the model has been condensed to conform to the standard length of chaffinch song by condensing the middle phrase of the tree pipit song to two notes instead of four. This song became still further 'tightened up' and shortened by the beginning of May (Fig. 11).

The reason why chaffinches do not imitate and acquire songs from other species in the wild now seems fairly evident. There is little doubt that they restrict their imitativeness to the right models as a result of being responsive only to notes of approximately the right tonal quality. It is interesting that the imitation of the tree pipit song just referred to is the best copy of an alien song so far obtained. Here the tonal quality of the model was right, although the song itself was much too long and the phrasing of the notes of the model abnormal from a chaffinch point of view.

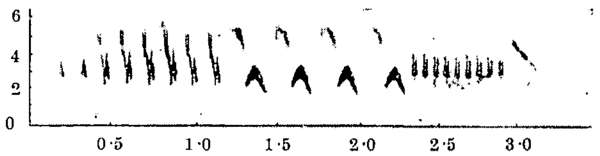

Fig. 9

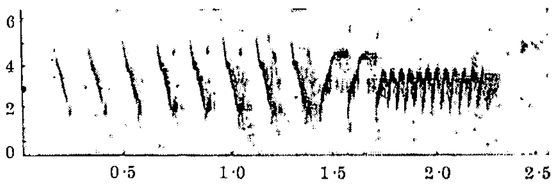

Fig. 10

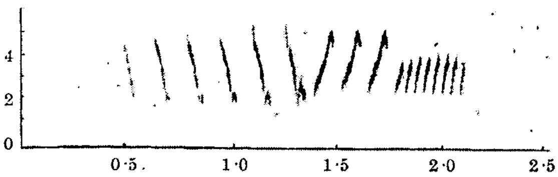

Fig. 11

Fig. 9. Song of Continental tree pipit (*Anthus trivialis*) used for tutoring

Fig. 10. 'Copy' of tree pipit song produced by chaffinch *R/R* after tuition on 'song tutor', April 21, 1956

Fig. 11. 'Improved' tree pipit copy. *R/R*, May 3, 1956

To summarize this work with the 'song tutor', it can be said that in eleven experiments carried out over the years 1955–57 and involving thirty-four wild autumn-caught first-year males, the only positive effect obtained (in the sense of a significant similarity between model and mimic) occurred in two experiments (seven birds) only, and in these two the model was a normal chaffinch song. Of the remaining ones (nine experiments, twenty-seven birds) the models were always abnormal—the songs being artificial, re-articulated or reversed—and the results were always negative. The contrast when hand-reared isolated birds are used is striking. Thus during 1954–59, thirteen experiments involving sixteen hand-reared birds were carried out using similar song models. Of these, ten experiments (eleven birds) were positive in the sense of yielding a significant effect. The remaining three experiments (five birds) gave a negative result.

The counter-singing that occurs between birds in adjacent territories is an important factor in stimulating and restricting the imitative abilities of chaffinches. When a chaffinch has acquired more than one song-type, each song-outburst consists of a sequence of one song-type followed by a sequence of another. When songs are played back to a chaffinch, we find that those songs which it uses most frequently itself are the most effective in evoking song[5]. A chaffinch in the wild will thus tend to reply to a neighbour with that song of its own repertoire which most nearly resembles the song of its rival.

It is suggested that, with the more 'imitative' finches such as the bullfinch (*Pyrrhula pyrrhula*), hawfinch (*Coccothraustes coccothraustes*) and to some extent greenfinch (*Chloris chloris*), the song, while functional in co-ordinating the breeding cycle and behaviour of the mated pair, is of less importance as a territorial proclamation. Thus in some respects it resembles the sub-song rather than the full song of the chaffinch; similarly, contamination with alien notes can be tolerated to an extent which might be very disadvantageous in a strongly territorial song that must maintain its character as a reliable specific recognition mark. A preliminary study of a number of species of buntings shows that many of the species, for example, reed and corn buntings (*Emberiza schoeniclus* and *E. calandra*), have songs which are highly stereotyped and completely innate. The song of the yellow bunting (*E. citrinella*) appears to consist of an integration of innate and learned components much as in the chaffinch. The buntings as a whole appear to have strongly territorial songs corresponding in function to that of the chaffinch.

Apart from a very few and partial exceptions, chaffinches can learn song patterns only during the first thirteen months of life, and towards the end of this time there is a peak period of learning activity of a few weeks during which a young chaffinch may learn, as a result of singing in a territory, the fine details of as many as six different songs. This special period of high learning ability is brought to an abrupt close by internal factors. It matters not whether a chaffinch has learned one or six songs by the time it is thirteen months old, it can afterwards learn no more, and so it remains with its one song or its six for the rest of its life. This restriction of learning ability to a particular type of object and to a sharply defined sensitive period recalls the phenomenon of imprinting.

The inborn recognition and performance of its specific song by the chaffinch involves (*a*) duration of approximately 2½ sec., (*b*) interval between songs of between 10 and 20 sec., (*c*) tonal quality (though this last may have been learned by the experience of the bird of the qualities of its own voice). The readiness with which the bird learns to divide its song into three sections and learns to attach a simple flourish at the end as an appropriate termination shows that there must be an imperfectly inherited tendency to respond to, and perform, the features of the normal song as soon as the singer is stimulated by hearing another bird. Such an inherited tendency would explain the basic similarity of the songs of the species throughout its range.

THE ELECTRON TEMPERATURE IN SCEPTRE III

By Dr. S. KAUFMAN and R. V. WILLIAMS
Research Laboratory, Associated Electrical Industries, Limited, Aldermaston

IN high-current discharges of the type observed in ZETA and SCEPTRE[1] thermodynamic equilibrium does not exist, and the ions and electrons may be at different temperatures. The Doppler broadening of spectral lines is evidence of large ion velocities, although it has yet to be shown conclusively that the motion is associated with a real ion temperature. On the other hand, no results have yet been published on the electron temperature T_e.

In general, it should be possible to determine T_e from a study of spectral excitation by electron impact, and qualitative variations in electron temperature for different conditions of the SCEPTRE discharge were at first observed from the relative strengths of spectral emission in different stages of ionization (for example, O V/O IV)[2]. However, an absolute determination of T_e is generally difficult because of the multiplicity of processes which can populate an atomic level. It is proposed that this problem can be simplified if a suitable atom of the He I iso-electronic sequence is chosen. From a preliminary measurement of the absolute intensity of a C V spectral line, T_e has been estimated to be $2 \cdot 5 \times 10^6$ deg. K. to within a factor 2, on making the basic assumption that run-away electrons do not contribute appreciably to the excitation.

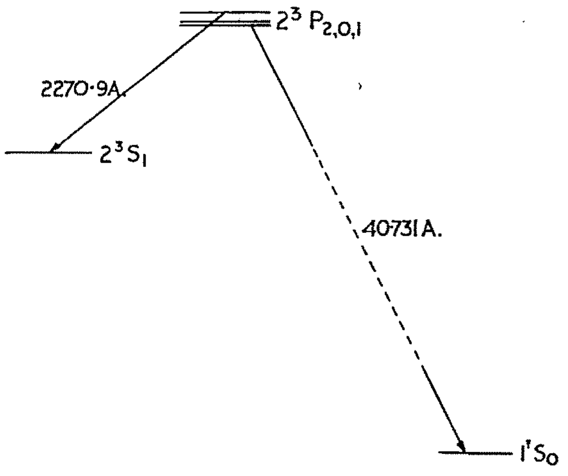

Fig. 1. Partial Grotrian diagram of the He I iso-electronic sequence. Wave-lengths and relative positions of the triplet lines refer to C V

Atoms of the He I iso-electronic sequence are particularly stable. For example, while the ionization potential of C IV is only 64·5 eV., the lowest excitation potential (E_{12}) of C V is 304 eV., excluding the neighbouring 2^3S metastable level (Fig. 1). Thus, cumulative processes from previous stages of ionization are comparatively unimportant and it is assumed that the C V spectrum will not be excited appreciably until all the carbon atoms are in the ground-level $1\,^1S$ of C V (cf. the conditions in Wolf-Rayet stars[3]). We also suppose that the 2^3P_2 level of C V is filled entirely by electronic excitation from this level (population N_1). The competing processes which populate the 2^3P_2 level (cascade from upper levels and electronic excitation from the 2^3S level) and de-populating processes other than radiation (namely, electronic excitation and super-elastic collisions from the 2^3P_2 level) are neglected; their effect on the measured temperature is considered below. The transition $1\,^1S_0$–2^3P_2 is forbidden for dipole radiation. In the steady state which is attained after about 10^{-7} sec., the rates of electronic excitation of the 2^3P_2 level and radiation from this level by the line (2^3S–2^3P_2) at 2270·9 A.[4] will therefore be equal. Hence, the specific intensity I of this line is

$$I = 2\left(\frac{2kT_e}{\pi m}\right)^{\frac{1}{2}} N_1 n Q_{12} h\nu \left(1 + \frac{E_{12}}{kT_e}\right) \exp\left(-\frac{E_{12}}{kT_e}\right)$$

where k is Boltzmann's constant, m the electron mass, n the electron concentration, h Planck's constant and ν the frequency of the spectral line. The cross-section Q_{12} for electron impact from the 1^1S to the 2^3P_2 level is finite at the threshold energy and, for simplicity, is regarded as invariant with energy above threshold. Measurement of the absolute intensity of this C V line therefore permits an evaluation of T_e, providing the other parameters are known.

The line at 2270·9 A. was first identified on several spectrograms but was faint and broad; the other members of the triplet were too weak for exact identification. To demonstrate this method of estimating T_e, a preliminary experiment was conducted under discharge conditions where the excitation of the O V line (2781 A.) was intense, namely, deuterium at a pressure of 1·4 millitorr, the condenser bank charged to 25 kV., turns ratio 16 : 1, initial toroidal magnetic field of 500 oersteds and peak gas current $1 \cdot 2 \times 10^5$ amp. Methane at a partial pressure of 3×10^{-5} torr was added to the deuterium to strengthen the C V emission and provide an estimate of N_1. The temporal and spatial intensity distributions of the line at 2270·9 A. were obtained with a combination of a monochromator and a photomultiplier. The intensity I of this line at peak excitation averaged over the central region of the torus was measured to be 4×10^2 erg. sec.$^{-1}$ cm.$^{-3}$. Peak excitation occurred at approximately peak current, which was unchanged by the introduction of the methane. From the above relation and taking the value of Q_{12} at threshold to be $1 \cdot 8 \times 10^{-17}$ cm.^{2} $(0 \cdot 2 \pi a_0{}^2)$, T_e was found to be $2 \cdot 5 \times 10^5$ deg. K.

It is fortunate that at about this temperature the exponential factor in the above relation is extremely sensitive to the smallest change in T_e. Therefore, only the order of magnitude of $N_1 n Q_{12}$ need be known and considerable latitude can be permitted for the magnitude of competing processes. In the estimation of N_1 we are justified in assuming that most of the carbon atoms are in the C V ground-level, for the excitation of the O IV line at 3063 A. was a minimum at the torus axis. If instead of the above excitation mechanism it is assumed that the dominant excitation of the 2^3P_2 level is from the 2^3S level, the electron temperature can still be calculated because the populations of the 2^3S and ground-levels are governed approximately by Boltzmann's distribution law. Even if Q_{m2}, the cross-section for this process is taken as large as 100 Q_{12}, T_e is only altered to $2 \cdot 0 \times 10^5$ deg. K. Super-elastic collisions from the 2^3P_2 level are relatively unimportant for the assumed value of Q_{12}. If this process were very much greater so that it predominated over radiation, the populations of the 2^3P_2 and ground-levels would also be determined by Boltzmann's distribution law: the calculated temperature would again be $2 \cdot 0 \times 10^5$ deg. K. The principal cascade effect to the 2^3P_2 level, namely, from the 3^3D term, is scarcely likely to alter the population of the 2^3P_2 level radically, for it is situated 50 eV. above this level. This large energy jump also reduces the compensating process of electronic excitation from the 2^3P_2 level. If the estimation of the coefficient of the exponential in the equation is considered to be in error by a liberal factor, namely, either 10^{-3} or 10^3, a range of $(1 \cdot 7–5 \cdot 2) \times 10^5$ deg. K. would be the uncertainty in T_e. For higher values of T_e, it will be important to know the magnitudes of Q_{12}, Q_{m2}, N_1 and n more exactly. Further theoretical and experimental work is in progress and it is hoped to publish a fuller account at a later date.

A value of $2 \cdot 5 \times 10^5$ deg. K. for T_e is consistent with qualitative observations of the plasma's electrical conductivity and O V emission. However, the need to explain the large Doppler widths which are observed is even more compelling than hitherto. Spitzer's suggestion[5] as extended by Gabor[6] that co-operative phenomena between the electrons and ions are responsible for the large ion velocities, need not be called into play.

We acknowledge our indebtedness to Dr. M. J. Seaton (University College, London) for having suggested to us the possible order of magnitude of Q_{12}, and to Prof. B. Edlén (University of Lund) for his assistance in the identification of the C V triplet. We are also grateful to Mr. T. P. Hughes for photographing the spectra, to Dr. A. A. Ware for his interest and comments on the manuscript, and to other colleagues of the Thermonuclear Section for their active help in running SCEPTRE III. We also acknowledge helpful discussions with our colleagues at the Atomic Energy Research Establishment, Harwell.

This work was supported in part by a contract from the Atomic Energy Research Establishment, Harwell, and is published with the permission of Dr. T. E. Allibone, director of this Laboratory.

RUDJER BOŠKOVIĆ INSTITUTE, ZAGREB

By PROF. IVAN SUPEK

President of the Council of the Institute

THE decision to found the Rudjer Bošković Institute was taken by the Yugoslav Federal Government in May 1950. At this time the building of the Boris Kidrič Institute, Vinča—the first institute for nuclear sciences in Yugoslavia—was almost complete, and that of the Jožef Stefan Institute in Ljubljana had just begun.

Although the emphasis is on nuclear physics, the Council of the Rudjer Bošković Institute intends to include activities in the fields of chemistry and biology. For this reason, laboratories for physical chemistry and biochemistry were built in 1952, and two years later two fairly large buildings, originally barracks, were adapted as biological laboratories.

The newly formed Council of the Institute wished to establish a firm basis for fundamental research in nuclear energy. The main problem was the need for scientific personnel on one hand and an insufficiently developed tradition of scientific training in the universities on the other. A large number of graduates, therefore, were sent abroad to continue their postgraduate studies. Most of them went to England, where they always found a ready welcome. For example, four of our students took their doctor's degree in experimental physics at the University of Birmingham.

Although three institutes for nuclear research work were under construction at the same time, the allocation of work among them was made at the very start, so that since then each has functioned as part of a larger organism.

As the Institutes in Vinča and in Ljubljana were chiefly interested in reactor physics, the Council of the Rudjer Bošković Institute decided at the end of

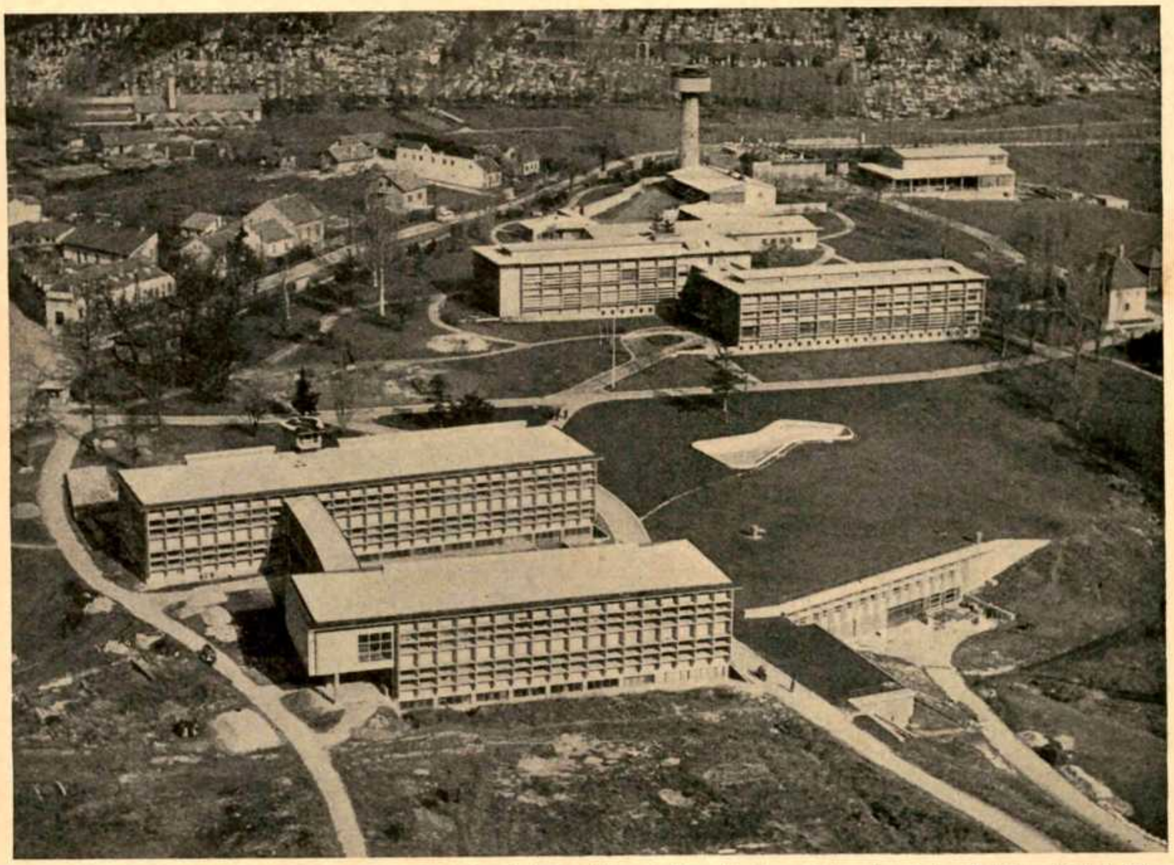

Fig. 1. The Rudjer Bošković Institute. The physical and chemical laboratories with the service and workshop buildings behind. The cyclotron house is underground on the right, the natural formations providing adequate screening

1950 to build its own cyclotron for the investigations in nuclear physics as well as for specialized techniques in the application of radioactive isotopes. A group of young engineers, therefore, after seeing some cyclotrons in Europe, made a detailed plan for a cyclotron to be constructed by themselves. This cyclotron will be the biggest machine for nuclear research in Yugoslavia, planned and built within the country, and with most of the instruments provided by domestic industry. The deuteron beam is expected to have an energy of 16 MeV. The cyclotron is to be a variable energy machine.

Two experimental groups for research on nuclear structure have been formed; their work will centre around the cyclotron and the 200 kV. neutron generator. In addition, there is a theoretical department which is working on the theory of fields, the study of nuclear structure, and the theory of metals.

From the beginning there has been a tendency to manufacture as much of the apparatus as possible within the Institute. A well-equipped Electronics Department was therefore organized as soon as the Institute was founded. Various types of counters, scalers, as well as other apparatus for nuclear research work have already been made. Work on transistors is also in progress.

There are two groups for physical chemistry: one dealing with structure analysis, the other with technological problems, especially those concerning nuclear raw materials. Great pains are being taken in the production of semi-conductors and of other crystals which are of importance to industry. New

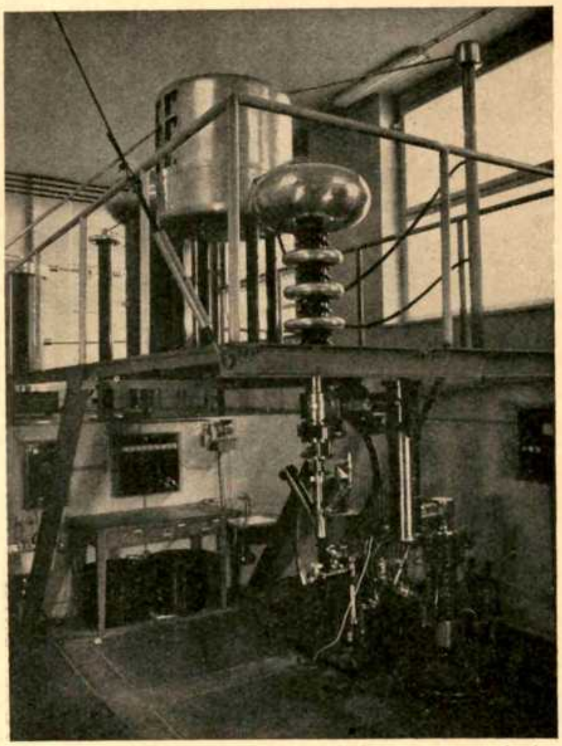

Fig. 2. One of the accelerating machines in the pure physics section

methods for the study of chemical processing problems are being introduced. Work in the tracer laboratory has been going on for three years in collaboration with the biology department, primarily on the compounds labelled with carbon-14.

Besides these investigations with weak radioactivities, a group for radiochemistry has been formed which will study materials which have been irradiated with the cyclotron and the application of radioactive isotopes in chemistry.

The basic task of the biochemical department is the synthesis of protectors against radiation, and recently emphasis has been laid on antibiotics. Investigations with labelled organic compounds are also in the biochemistry programme.

The research work in biology is mainly concerned with basic effects of radiation on living organisms, single-cell organisms and viruses being studied on one hand, and complex organisms on the other. Some of the biological work was begun in the Medical Institute of the University of Zagreb, and is now being continued in the Department of Biology.

The Scientific Council has always believed that the Institute and the University should be united by common efforts in research work as well as in the training of young scientists. In 1953 the University and the Institute Council decided to unite their efforts in the fields of work common to them and a postgraduate school was organized in the Institute in 1957.

The Institute is financed by the Federal Atomic Energy Commission, which also approves the annual research plans and co-ordinates work with that of other institutes in the country. Industry and other institutions, besides the Commission, support research work outside the field of nuclear energy.

At present about 400 people are working at the Institute. The number of scientific personnel is about 140 and it is hoped that this will increase next year. Technical staff working in the laboratories number about 60, and there are about 60 workers employed in the Institute workshops. Eventually the Institute will employ about 600 people.

Some experts of the Great Powers may look sceptically upon the efforts of small countries. Certainly, we cannot enter the race in big technical undertakings in the field of nuclear energy and we do not wish to. Our intention is to take part in fundamental research and to help build a solid basis for peaceful applications. But still more than this, the present state of the world, split into armed camps, has disrupted the internationalism of science. In this situation, on the verge of the suicide of the whole of mankind, the renaissance of a universal spirit is an aim, in the realization of which small countries like Yugoslavia can help a great deal.

NEWS and VIEWS

Research Association of British Rubber Manufacturers: Dr. J. R. Scott

The recent announcement that Dr. W. F. Watson has been appointed director of research of the Research Association of British Rubber Manufacturers might suggest that the rubber industry would be losing the services of Dr. J. R. Scott, but his many friends will be glad to know that this is not the case, because he is to be appointed to the newly created post of scientific adviser to the Research Association. Those who have followed the advance of international standardization will have realized how much progress has been made by Committee *ISO/TC/*45, on Rubber, of the International Organization for Standardization. This has been largely due to the painstaking work which Dr. Scott has put in as leader of the United Kingdom delegation. The patient and well-informed manner in which he dealt with international differences in opinion serves as a model of diplomacy which could well be followed by others. He is expected to lead the delegation to the next meeting, to be held in the United States in the autumn of 1959. As Dr. Scott will not be retiring in the near future, it is sufficient to note that he has already had thirty-five years service with the Association, and that he was the second holder of the post of director of research, succeeding the late Mr. B. D. Porritt on the latter's death in 1940.

Dr. W. F. Watson

Dr. W. F. Watson, who has been appointed third director of research, was born in Fifeshire in 1923 and obtained his Ph.D. when he was twenty-two, working at the University of Aberdeen under Prof. (now Sir Harry) Melville. He studied the theoretical treatment of copolymerization kinetics, the retardation and inhibition of polymerization reactions, the polymerization of methyl methacrylate initiated by its own polymer, and the diradical nature of photochemical and thermal polymerization. His work at Aberdeen was followed by a two-year postdoctorate fellowship at the University of Minnesota, sponsored by the United States Office of Naval Research, involving the absorption spectra of highly purified chlorophyll, for which he was awarded the D.Sc. degree of the University of Aberdeen at the age of twenty-six. His present work at the British Rubber Producers' Research Association is especially notable for studies of the way in which mechanical energy can be used to rupture molecular linkages, and he was the first to prove that this process occurred under the conditions obtaining in the mastication process. This development has opened up possibilities of obtaining interesting new materials, which have been confirmed on a commercial scale, and no doubt Dr. Watson will be continuing this work, as well as developing his novel single-rotor rubber mixer, at the Research Association.

Geology at the Imperial College of Science and Technology: Dr. John Sutton

Dr. John Sutton, reader in geology in the University of London, has been appointed to the University chair of geology at the Imperial College of Science and Technology, London, vacated three years ago by Prof. H. H. Read, whose work is described in *Nature*, 176, 490 (1955). Dr. Sutton has been associated with the Imperial College throughout his career as undergraduate, postgraduate research student, lecturer and reader—with a non-academic interruption by service in the Royal Electrical and Mechanical Engineers separating the first two stages. His early research work, done in collaboration with Dr. Janet Watson (Mrs. Sutton), dealt with the structural, metamorphic and plutonic history of the most ancient rocks, first of the Lewisian of the Scottish Highlands and then of the basement of East Africa. During the past decade, Dr. Sutton has built up at the Imperial College a research school concerned with the investigation in great detail of the structural history of the Moine Series of the Northern Highlands. Under his leadership, the complex history of this famous group of rocks has been patiently unravelled by meticulous field-work over considerable areas east of the Moine Thrust, and a firm foundation has been laid for a complete structural synthesis of Britain's most extensive formation. Agreeable to the definition of geology as earth-history, this work is marked by an appreciation of the importance of the timing of events in the production of crystalline schists. Under Dr. Sutton's direction in the field and the laboratory, a continued development of fundamental research in the metamorphic and plutonic rocks can confidently be expected at the Imperial College.

Seals and Nets

In its last annual report the Nature Conservancy reluctantly accepted the desirability of experimenting in strictly limited measures of control of the Farne Island grey seal population and recommended, as an experimental and interim measure, that further increases in the grey seal should be limited by an annual cull of 300 calves, if authorized by the Minister of Agriculture, Fisheries and Food by Order under the Grey Seals Protection Act, 1932. It also recommended continuation of research and observations on seals as at present and a new attempt, sponsored by the Scottish Home Department, to discover means of protecting nets against seals. Such an Order was laid before the House of Commons on July 10 and on July 28 a motion against the Order was made by Mr. A. Blenkinsop, who, in asking what the Government was doing to encourage further research into the problem and to strengthen nets, alleged that it had refused a grant to the Nature Conservancy to enable it to carry out this research work more effectively. Widely varying views were expressed in the debate, in which the risk of exterminating the grey seal, as had happened on the north Cornish coast, was recognized by supporters and opponents of the Order. The motion was withdrawn in view of the explanation by Mr. J. B. Godber, Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food, that no final decision had been taken as to the merits of culling as a means of controls and his undertaking to look into the possibility of assistance to further research work.

Committee on Grants to Students

The Ministry of Education and the Scottish Education Department announce that the Committee on Grants to Students set up recently under the chairmanship of Sir Colin Anderson (see *Nature*, 182, 20; 1958) is now ready to receive written evidence. Any interested persons or bodies are invited to submit a memorandum to the secretaries (for England and Wales, Mr. D. Neylan, Ministry of Education, 14 Cornwall Terrace, London, N.W.1, and for Scotland, Mr. G. A. T. Hanks, Scottish Education Department, St. Andrew's House, Edinburgh 1), if possible not later than November 30. The terms of reference of the Committee are: "to consider the present system of awards from public funds to students attending first degree courses at universities and comparable courses at other institutions and to make recommendations". Among the questions which the Committee will be considering are the kinds of awards to be made from public funds, the method of selecting students for such awards and the principle of the hardship test required by the law as it now stands.

Adventures in Science

The Smithsonian Institution has just published a new popular science booklet for young people, designed to show "that science can be exciting and that science can be fun". Entitled "Adventures in Science at the Smithsonian", the illustrated 24-page booklet tells about a few of the scientific milestones that have marked the progress of civilization and shows part of the outstanding role that the Smithsonian has played in the advancement of science since its founding in 1846. Planned to appeal primarily to children in junior schools, "Adventures in Science" not only presents information about many different sciences in simple, easy-to-read form but is also extensively illustrated in colour with objects from the Smithsonian's collections. The booklet can be read in two ways—from front cover to back, or from back cover to front. The natural sciences occupy the first half of the publication, while the physical sciences and engineering occupy the second half. If the reader begins at the back page, he starts in the present—"Tracking Earth Satellites"—and reads back into time. If he starts at the front, he journeys from "The Dinosaur Age" to the present. The authors, E. John Long and George Weiner, have simplified the often prolix terminology of science. For example, the subject of anthropology is covered in the section entitled "Searching for Cave Men", and astronautics, or rocketry, is discussed in "Into Space". The price for single copies is 25 cents.

Laws in Social Science

One of the main points made by Sir Alexander Carr-Saunders in his recent Eleanor Rathbone Memorial Lecture at the University of Liverpool ("Natural Science and Social Science". Pp. iv+15. Liverpool University Press, 1958. 3*s*.) is that, despite many attempts by social scientists to discover laws and law-like correlations by using the procedures of the natural sciences, "nothing remotely resembling a law of the natural sciences has yet been produced". Carr-Saunders agrees with J. S. Mill who, in his "System of Logic", subjected the possibility of using natural science procedures in the social sciences to exhaustive analysis. His conclusions were that, because of what Mill called "the complication of causes" and of the impossibility of insulating the variables concerned from the large influences of extraneous factors, no laws can be established in the social sciences in this way. It is not surprising that none has been discovered. "If such laws could be discovered they would appertain rather to a world of ants than to a world of men."

Work of Sir Edmund Whittaker

The *Proceedings of the Edinburgh Mathematical Society* of June 1958 is a worthy memorial to the late Sir Edmund Whittaker. An obituary notice by D. Martin is followed by papers on various aspects of Whittaker's work: harmonic functions (G. Temple); automorphic functions (R. A. Rankin); algebra and numerical analysis (A. C. Aitken); relativity (J. L. Synge); physics and philosophy (J. McConnell). Few mathematicians of our time have matched Whittaker's clear vision and deep knowledge of the whole field of modern mathematics. To young men he was always an inspiration, and to ensure that this inspiration shall not be entirely lost, his family has founded a Whittaker Memorial Prize for the encouragement of young mathematicians in Scotland; details are given in this number of the *Proceedings*.

The National Museums, Ceylon

The annual reports of the National Museums in Ceylon for 1956 and 1957 (pp. 20+5 plates. 70 cents. Pp. 23+2 plates. 70 cents. Colombo: Government Publications Bureau, 1957 and 1958) record steady but not spectacular progress in all departments. The most outstanding discovery yet made in Ceylon was that of a Stone Age kitchen-midden in the Balangoda District containing a number of ceremonial burials in a flexed position. The skull is being reconstructed at the American Museum of Natural History and it is hoped that a carbon-14 test will be carried out in Britain. The Museum Week sponsored by Unesco in October 1956 was duly observed and important and instructive talks were given on Radio Ceylon.

Museum of Applied Science at Victoria

The annual report of the Museum of Applied Science of Victoria for the year ended June 30, 1957 (pp. 30. Melbourne: Museum of Applied Science of Victoria, 1958), is up to date, as it opens with a photographic illustration of a model of a space satellite now included in the museum collections. Another fascinating exhibit is a model of an oxygen atom with its twenty-four particles in rapid motion. Special exhibits were also displayed for the benefit of visitors to the Olympic Games in Melbourne in 1956. A series of large portraits of eight famous scientists, ranging from Galileo to Einstein, attracted much attention. The Museum has been fortunate in achieving two of its objectives of many years—the provision of a convenient store of adequate size and a hoist for moving massive objects to and from the main floor.

Technical Information Systems

The Office of Scientific Information of the National Science Foundation has issued under the title "Non-Conventional Technical Information Systems in Current Use" (pp. v+43. Washington, D.C., 1958) a report briefly describing twenty-five representative systems of new design, covering the principles of operation of each system, the equipment and man-power required, the size of the group served and of the file and its rate of growth, with bibliographical references to any published information on the system. The report is purely factual and includes no comment or criticism of the systems described. Among these are the mechanized searching system for patents on steroid compounds used at the United States Patent Office, the hand-sorted punched-card file for geochemistry maintained at the United States Geological Survey, the mechanized indexing system for literature in pathology and biochemistry, using the *IBM* 101 statistical machine at the Documentation Centre of the Schering Corporation, and the 'peek-a-boo' system of co-ordinate indexing used, for chemical compounds tested, by the U.S. National Institutes of Health cancer chemotherapy programme.

Egyptian Scientific Institutions

To assist men of science who are interested in the development of science in Egypt, the Middle East Science Co-operation Office of Unesco has published a survey of all the scientific institutions in Egypt (pp. 149. Cairo: Unesco Science Co-operation Office, 1957). The institutions listed are concerned with teaching and research not only in the fields of pure science but also in engineering, agricultural and medical sciences. With the exception of various scientific societies, all these institutions are government bodies. The survey explains how scientific institutions are controlled by the Ministry of Education and also gives a clear account of the national educational system. Among the institutions described are the universities, the Science Council, the National Research Centre, Desert Institute, Atomic Energy Commission, Ministry of Agriculture, Ministry of Industry (Geological and Mineral Research Department, Mines and Quarries Department), Ministry of Commerce (Chemical Department), Ministry of Public Works (Nile Control Department), Ministry of Public Health, Ministry of War, the Egyptian Sciences Association, l'Institut d'Egypte, and the Egyptian Academy of Science. Names of leading members of the staffs of these organizations are included.

University Theses

The Committee of the University and Research Section of the Library Association set up in 1952 a small sub-committee to investigate ways and means of publishing detailed information about the contents of theses accepted in British universities and increasing their availability. A report by this sub-committee, published in the *Library Association Record* (60, 13; 1958), expresses the opinion that the arrangements with regard to theses are generally too haphazard to be entirely satisfactory and that it should be possible for the universities to adopt a uniform plan to render such information more comprehensive and regularly available. The sub-committee was aware of the "Index to Theses accepted for Higher Degrees", published annually by Aslib since 1950–51, and noted a scheme operated by University Microfilms in the United States in which some eighty universities and associated institutions participate, but inquiries as to the feasibility of a similar scheme in the United Kingdom met with a disappointing response. The report summarizes the difficulties which must be overcome in regard to accessibility or secrecy, copyright, etc. It stresses the importance both of the Standing Conference of National and University Libraries persuading British universities to accept a desirable standard of availability and also of the work of the Department of Scientific and Industrial

Research in improving communication between the universities and government research establishments. A new commercial but selective scheme for microfilming dissertations is briefly described, which could be adapted to meet the requirements of individual universities and eliminates the need to charge a microfilming fee.

Computer Training Centre

Bradenham Manor, the property of the National Trust, has been leased to the British Tabulating Machine Co., Ltd., for use as a Hollerith Computer Training Centre. On July 24 the Centre was opened by Lord Halsbury, managing director of the National Research Development Council, who said that the old idea that a trainee learnt his job by copying what his predecessor could be seen to be doing has no room in the field of computer training. Training on modern, almost academic, lines is what is required and such training the Bradenham centre would provide. Some 3,000 people per annum undergo training in the use and applications of mechanized accounting equipment at the five educational and training establighments maintained by the British Tabulating Machine Company's resources. Other facilities will become available as the result of the proposed merger with Powers-Samas.

Rugby School Natural History Society

P. R. M. Pattisson, a scholar at Rugby, has carried out experiments to determine the reactions of *Gammarus* sp. to water currents. The apparatus consisted of a double horseshoe-shaped trough about 7 ft. long, containing water circulated by a paddle-wheel. The water was about ½ in. deep. The speed just above the bottom was measured by timing the movement of a small piece of pumice-stone weighted with 'Plasticene' over a measured distance. Experiments were carried out in the clear straight side of the trough which was marked off in inches and showed that the swimming speed increases linearly with the current. While swimming, *Gammarus* is able to gain ground for any current speed. The rate of increase in swimming speed is less than the corresponding increase in current; the animal gains ground more slowly at the higher current speeds. The respiration of *Tubifex* and *Culex* sp. has been investigated by A. M. Roberts, another scholar at Rugby. The Report for 1957 (Report of the Rugby School Natural History Society for the year 1957. Pp. 28+1 plate. (Ninety-first issue.) Rugby: Rugby School Natural History Society, 1958) contains details of these two investigations as well as reports of all the many sections affiliated to the Society. Their activities do credit to scholars and staff.

Circulation in the Black Sea

It is usually assumed that the Black Sea in its deeper part (below 200 m.) consists of stagnant fœtid waters rich in hydrogen sulphide. This led to a suggestion that the Black Sea may be utilized as a depository for the atomic waste. Arguments showing the erroneous conception of 'buried' bottom waters of the Black Sea are brought forward by V. A. Vodyanitzky (*Priroda*, 2, 46; 1958), who presents strong evidence in favour of the existence of convexion currents producing a vertical circulation of the waters of the Black Sea.

Geological Age

Eduard Suess in his "Face of the Earth" postulated the existence of "the most ancient vertex of the Eurasian folds" occupying the mountain-crescent fringing Lake Baikal in the south. This vertex, formed by folded mountains of the Pre-Cambrian age, fringes the southern border of the stable "Augara Land'. As outlined by V. T. Mordovsky (*Priroda*, 3, 85; 1958), this conception, based on the original works of I. D. Chersky and V. A. Obruchev, must be completely reconsidered in the light of subsequent interpretations carried out by L. de Launay, M. M. Tetiaev, A. N. Churakov and N. S. Shatsky. According to the Tectonic Map of the U.S.S.R. edited by Shatsky and published in 1957, the exposed portions of the Pre-Cambrian 'Augara Land' are exposed only in the Anabar, Sayan and Aldan massifs, while its remaining parts are covered by later stratified unfolded deposits. At the same time, the greater part of the area of the alleged 'ancient vertex" must be considered to be formed by rocks folded during the Baikalian orogenesis (Early Cambrian to late Proterozoic) and Caledonian orogenesis (late Palæozoic). "Thus", writes Mordovsky, "the ancient vertex of Asia, as understood by Chersky, Obruchev and Suess, does not exist. The Siberian Platform, together with the Anabar massif and the Aldan shield, is one of the most ancient areas in the northern Asia".

Root–Shoot Relationships

The effect of removing part of the root system on the subsequent growth of the root and shoot systems has been investigated by E. C. Humphries (*Annals of Botany*, N.S., 22, 251; 1958). When some 50 per cent of the roots of barley and rye were removed, the growth-rate of the remaining roots was the same in intact plants; but the growth-rate of the shoot decreased progressively as more and more roots were removed. When the number of roots removed exceeded 50 per cent, there was a decline in the rate of root growth, though this was less marked than that of the shoot. Comparable results were obtained in experiments in which the lateral roots of tomatoes were removed; but in this species a 40 per cent removal of laterals was critical for maintenance of growth in the remaining root system. The author also reports that the uptake of potassium, in barley plants with parts of the root system removed, was closely proportional to the increase in dry-matter when the nutrient supply is not limiting; but, with low nutrient supply, the potassium uptake was less than the dry-matter increase.

Auxins in Bean Embryo Development

M. Furuya and K. Soma have contributed some interesting new observations on the effects of various auxins on the development of bean (*Phaseolus vulgaris*) embryos grown *in vitro* (*J. Fac. Sci. Univ. Tokyo*, Sect. 3, 7, 163; 1957). Dormant embryos were removed from the cotyledons and cultured either intact, or as four separate regions or segments, namely, the apical portion, including the first foliage leaves, the hypocotyl, the short basal transitional region, and the radicle. White's solution, with the vitamins omitted, was used, together with individual additions of β-indolylacetic acid, sodium 2,4-dichlorophenoxyacetate (2,4-D) and sodium α-naphthylacetate at different concentrations (10^{-3}–10^{-11} mole per litre). Liquid and solid media were both used and cultures were maintained either in continuous darkness or in 12 hr. of light a day. Measurements of growth and of morphological and histological developments are recorded and illustrated. Among the abnormal developments observed, especially at the higher concentrations of auxin, were the formation of tumourous and callus tissues, disorganizations of normal tissue differentiation, and formation of adventitious roots, but no induction of buds is reported. Attention is directed to the different reactivities of different regions of the embryo according to concentration of auxin and cultural conditions. The three auxins tested had generally comparable effects on the growth and differentiation of embryos, namely: complete inhibition of growth; inhibition in meristematic tissues, including the procambium, but extensive activation in mature tissues; activation in meristematic tissues, including the formation of adventitious roots; and regulation of growth-rate, these being in the order of decreasing auxin concentration. The results obtained are discussed fully in relation to contemporary views on auxin action.

Control of Dollar Spot Disease (*Sclerontinia homoeocarpa*)

Trial work with a new fungicide, cadmium chloride/urea, has recently been completed by the Sports Turf Research Institute (*Sports Turf Bulletin*, 41, April–June, 1958) for the control of dollar spot disease. Outstanding results were obtained from seven (monthly) applications of the fungicide on the bowling green of the Briton Ferry Steel Co., Ltd., in Glamorgan. The green (originally of sea-marsh origin) still contains a proportion of the original sea-side bents and fescues with an admixture of annual meadow grass. Although in good condition each summer, the fescue has been progressively weakened by attacks of dollar spot disease. Work with the cadmium chloride/urea fungicide started in April 1957. Further applications at the same rate were made in May, June, July, August, September and October. The fungicide spray was combined with the regular application of fertilizer—three evenly spaced applications of fertilizers containing a high proportion of readily available nitrogen. When examined in November, the turf was found to be free from visible signs of the dollar spot disease. There were no signs of other diseases such as *Fusarium* patch and *Corticum*. The same fungicide was effective in controlling dollar spot disease on bowling greens in Yorkshire and Lancashire. On other greens good control of the disease has been obtained, but where an insufficient number of applications has been made, the disease has re-appeared later.

Colour Changes in Teleosts

The control of colour changes in the lower vertebrates, including the teleostean fishes, has received a considerable amount of attention, and various different and even conflicting theories have been put forward to explain it. In a recent study, Priscilla Rasquin (*Bull. Amer. Mus. Nat. Hist.*, 115; 1958) has approached the problem from a different aspect and, instead of studying one or two species in detail, has surveyed a wider field. The memoir is divided into two separate parts. Part 1 is the study of the histomorphology of the pineal complex of thirty-three species of teleosts, including freshwater and marine forms. In general, the extent of the specialization of the pineal organ (epiphysis) is related to the degree of transparency of the overlying tissues and it exhibits a wide range of variation. Experiments on pinealectomy in *Astyanax* show no appreciable effect upon pigmentation, and while there is some evidence of secretory activity in the pineal organ in some species there is none of an endocrine function. Part 2 is a study of the effects of the injection of adrenalin in thirty-five different species and also of intermedin and a series of mammalian pituitary hormones. With adrenalin three groups can be distinguished in which there is: (1) a concentration of granules in the melanophores; (2) a concentration in the internal melanophores only; (3) no effect. In all species there was a response in the lipophores to adrenalin but in one group the response was dispersion and in the other concentration of the pigment granules. With intermedin all species showed dispersion in the lipophores, but the melanin granules in the chromatophores in four species showed concentration and others gave no reaction. These observations show the need for further investigation, for the responses in one species need not be duplicated in another, and it is dangerous to argue from the particular to the general. Some of the photomicrographs in the ten plates are not good, and most would be more useful if labelled.

Continuous-writing Streak Camera

An improved streak camera for the study of fast self-luminous events has been developed by Beckman and Whitley. It is intended primarily for the study of explosions, shock tube, spark discharge and similar phenomena. Standard 35-mm. film, arranged for daylight loading and unloading, is used. The image is swept on to this film by a rotating triangular mirror driven by a high-speed turbine. Several types of these are available—the fastest one, ranging from 200 to 5,500 revolutions per second, is driven by helium gas. This arrangement produces a maximum writing rate of approximately 8 mm./μsec.; and a maximum time resolution, using a 0·004-in. wide slit image and film having a resolution of 75 lines per mm., of $2 \cdot 5 \times 10^{-8}$. The camera has a control equipment which includes an events-per-unit-time meter for accurate measurement of the mirror speed to provide a determination of writing-rate; mirror-speed adjustments; and controls for the capping shutter and the explosive-actuated blast shutter, used to prevent rewriting in the case of events of long duration.

Cometary Spectra

In a recent paper entitled "Molecules in the Solar System" (*Cont. Dominion Astrophys. Obs., Victoria, B.C.*, No. 51), A. McKellar discusses gaseous molecules in comets and in planetary atmospheres, including that of the Earth. The spectra of comets are characterized by the occurrence of emission bands of molecules superposed on a background of reflected solar radiation. The spectra of comets are generally solar when their heliocentric distances exceed 3 astronomical units, but emission bands appear as the comet approaches the Sun. Generally speaking, heliocentric distance has proved the most useful parameter in describing the behaviour of the molecular emissions.

Dealing with the source of cometary gases, reference is made to Whipple's cometry model (*Astrophys. J.*, **111**, 375 ; 1950, and **113**, 464 ; 1951), which envisages the nucleus as a conglomeration of frozen solids, such as water, ammonia, methane, carbon dioxide or carbon monoxide, and possibly other materials, combined with meteoric matter, all initially at a temperature below 50° K. As the comet approaches the Sun, the frozen solids vaporize and so provide the parent molecules which, upon photo-dissociation, give the radicals the spectra of which we observe. Donn and Urey have suggested a modification of Whipple's model (*Astrophys. J.*, **123**, 339 ; 1956) to include both stable and reactive molecules, yielding radicals which could lead to actual chemical explosions to explain observed cometary activity. They give examples of a number of laboratory experiments involving NH and azides, OH and hydrogen peroxide, etc., that could conceivably occur if concentration of the necessary radicals and other molecules were present in the matrix. It appears, therefore, that solar radiation or corpuscles need only act as a trigger for the strongly exothermic reactions which provide their own excess of energy in the explosion.

Proceedings of the Royal Institution

The *Proceedings of the Royal Institution* are to be published three times a year in future instead of annually ; one advantage of the new procedure will be that the discourses will appear in print soon after their delivery. Thus, Vol. 37, Part 1, No. 165, which is the first to appear under the new arrangement, opens with the discourse on gemstones given by Sir Lawrence Bragg on January 31, 1958, and includes five other discourses given before Easter. It is also intended to publish once a year a famous discourse given at the Royal Institution a hundred years ago. The *Proceedings* are available to non-members at 8*s*. 6*d*. per issue, or 21*s*. a year, from January 1, 1959 (from the Royal Institution, 21 Albemarle Street, London, W.1).

"Rejection of the Peroxide Accumulation Hypothesis of Isoniazid Action"

Dr. Frank Winder, Laboratories of the Medical Research Council of Ireland, Trinity College, Dublin, writes : "In a communication under this title in *Nature* of April 26, p. 1203, Holmes and Rubbo state that 'Sodium nitrite . . . reduces free peroxide, and reacts rapidly with the catalase–peroxide complex . . .'. The first portion of this statement is true only when the *p*H is well on the acid side. To check this, 50 μgm. per ml. hydrogen peroxide were incubated with 500 μgm. per ml. sodium nitrite for 24 hr. in phosphate buffers over the *p*H range 5–7. The peroxide was then estimated by methods which did not involve acidification, for example, by using peroxidase or luminol. The nitrite caused no significant destruction of the peroxide in any of these buffers".

The Night Sky in September

New moon occurs on Sept. 13d. 12h. 02m. u.t., and full moon on Sept. 27d. 21h. 43m. The following conjunctions with the Moon take place : Sept. 4d. 21h., Mars 0·5° N. ; Sept. 16d. 07h., Jupiter 0·2° N. ; Sept. 19d. 15h., Saturn 3° S. In addition to these conjunctions with the Moon, Mercury is in conjunction with Venus on Sept. 5d. 02h., Mercury being 2·1° S., Venus with Regulus on Sept. 8d. 17h., Venus being 0·7° N., Mercury with Regulus on Sept. 10d. 09h., Mercury being 0·0° N., and Mercury with Venus on Sept. 18d. 06h., Mercury being 0·3° N. Mercury is favourably placed for observation during the first fortnight of the month, and is a morning star, rising at about 4h. ; during this period its stellar magnitude increases from +1·6 to −0·7. Venus is also a morning star, visible low in the south-east before sunrise. It rises at 3h. 30m., 4h. 10m. and 5h. 0m. on September 1, 15 and 30, respectively ; its stellar magnitude is −3·3. During the month its distance from the Earth increases from 149 to 156 million miles and the visible portion of the apparent disk from 0·947 to 0·982. Conditions for observation are rather unfavourable at the end of the month. Mars rises at 21h. 20m., 20h. 35m. and 19h. 45m. at the beginning, middle and end of the month, respectively. Its stellar magnitude increases during the month from −0·5 to −1·1, its distance from the Earth decreasing from 70 to 56 million miles. Mars enters Taurus on September 1, and continues moving eastwards among the stars ; it is south of the Pleiades on September 13–16. Jupiter is too close to the Sun for satisfactory observation. Saturn sets at 22h. 30m., 21h. 35m. and 20h. 40m. at the beginning, middle and end of the month, respectively ; it is near θ Ophiuchi. It has a stellar magnitude of +0·7 and a distance of 935 million miles from the Earth on September 15. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich : Sept. 7d. 01h. 46·6m., 115 Tau. (*R*) ; Sept. 9d. 02h. 12·8m., λ Gem. (*D*) ; Sept. 9d. 03h. 02·0m., λ Gem. (*R*) ; Sept. 21d. 19h. 08·9m., ρ Sgr. (*D*) ; Sept. 22d. 23h. 18·2m., β Cap. (*D*). *R* and *D* refer to reappearance and disappearance, respectively. The autumnal equinox occurs on Sept. 23d. 13h.

Announcements

The nineteenth national conference of the Council for the Preservation of Rural England, on "Rural Problems of the Moment", will be held in Cheltenham during October 16–18. Further information can be obtained from the Secretary of the Council, 4 Hobart Place, London, S.W.1.

The first electronic computer exhibition in Europe will be held at Olympia, London, during November 28–December 4. A business computer symposium will be held concurrently. Further information can be obtained from Mrs. S. S. Elliott, 11/13 Dowgate Hill, London, E.C.4.

The Institute of Physics, one of the constituent bodies of the British Nuclear Energy Conference, is arranging a Symposium in London on "Nuclear Fuel Cycles", on January 22 and 23, 1959. The papers which have been invited cater mainly for those working in the field, and will deal with the applied physics aspects of the fuel cycles which form the basis of the immediate nuclear power programme. Application to attend the Symposium should be made to the Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1. Proceedings of the Symposium will be published in the *Journal of the British Nuclear Energy Conference.*

COLONIAL TERRITORIES

THE report on the Colonial Territories for 1957–58* provides the usual conspectus of political, economic, financial and social developments in these territories against which the achievements to be recorded in greater detail in "Colonial Research, 1957–58" are to be considered. Some of this material, outlined in the 22-page chapter entitled "Research and Surveys", has also appeared in reports from various Colonial research organizations already noted in *Nature*, and for this reason, while this chapter in the present report is the one of most direct interest to the scientist, consideration of research in the Colonial territories is deferred until the fuller report, "Colonial Research, 1957–58", is published in due course.

Recruitment through the Colonial Office continued at the same general level as last year, but recruitment for the Federation of Malaya was gradually transferred to the High Commissioner for that territory. About the same number of administrative and medical officers were appointed as in 1956, but the number of educational appointments increased and the number of civil, mechanical and electrical engineers and agricultural officers recruited decreased. The total overseas appointments through the Colonial Office was 1,296 as compared with 1,286 in 1956, leaving 1,385 unfilled vacancies at the end of 1957, compared with 1,461 at the end of 1956. Training courses and attachments were arranged for 2,925 men and women in the service of overseas governments, compared with 2,752 in 1956.

The recession in world commodity prices in 1957 had little effect on the territories, and taking the year as a whole the prices of most Colonial products, except copper and sisal, were as high or higher than in 1956. Output continued to rise and the total gross domestic product is estimated as some 4 per cent above the 1956 level of about £3,100 million, the greatest proportionate increase being in the West Indian territories, where the value of exports rose by 12 per cent compared with a general increase of 2 per cent. The volume of exports of primary products rose only slightly.

After two years experimental work in the Western Region of Nigeria, 2,000 farmers were trained in their villages in spraying against capsid pest of cocoa. The extensive spraying campaign against blackpod continues, but control of swollen shoot disease has lost ground. Farmer-training in the control of blackpod and capsid on cocoa continued in the Eastern Region and about one-third of the 8,000 cocoa farmers in the Southern Cameroons sprayed their cocoa against blackpod disease with excellent results. In Kenya use of parathion sprayed from aircraft at night showed great promise for control of infestation by the Quelea bird (Sudan Dioch), and use of dieldrin for control of white stem borer of coffee and of DDT/BHC dust for cotton pests continued to spread in Tanganyika. A programme of research and control of the serious incidence of insect pests of cotton in the Aden Protectorate is in progress. Research continued into the most suitable types of fertilizers for individual soils and crops, and use of fertilizers continued to increase. The territories continued to receive expert assistance under the Expanded Technical Aid Programme. Two teams of experts visited Jamaica, Trinidad, British Honduras and Dominica to survey costing methods and research needs, respectively, of the citrus industries.

Effective control of the major epizootic diseases continued in the West African territories, but trypanosomiasis continues to be a serious problem in East and Central Africa.

Public expenditure on development continued at a high rate and expenditure from Colonial Development and Welfare Funds rose by about £1 million, but was still only about three-quarters of the annual average available under the 1955 Colonial Development and Welfare Act. New development plans were drawn up in Jamaica and Trinidad, and during the year power supplies became available for Kenya from the Owens Falls hydro-electric plant in Uganda. A new road from Western Uganda to the Belgian Congo was completed, work begun on the construction of a deep-water harbour in Barbados and the first hydro-electric plant in British Guiana came into operation.

Facilities for education increased in nearly every territory, as did the numbers using them. Of the 3,400 students in the two universities and three university colleges, 1,075 were in the University of Hong Kong, 749 at University College, Ibadan, 710 at the University College of East Africa, Makerere College, and 566 at the University College of the West Indies. Teaching and administrative staffs have also expanded, and University College, Ibadan, has now a fully established medical school with a new teaching hospital. In co-operation with the Nigerian College of Arts, Science and Technology, which was formally opened in November, a faculty of engineering is being established, and the University College of the West Indies is considering the establishment of a faculty of agriculture. Allocations to these university institutions under the Colonial Development and Welfare Funds for capital expenditure for the 1955–60 quinquennium total £6,853,000. The Royal University of Malta was the subject of an investigation by a Royal Commission, and the Governments of Kenya, Uganda, Tanganyika and Zanzibar jointly published a paper outlining their future plans for higher education.

Progress in preventive and social medicine has been in two main directions: by a widely developed attack on communicable disease by mass campaigns of treatment, immunization or destruction of insect vectors; and by much greater attention to the needs of the family and the individual through the medium of health centres, specialized clinics and an elaboration of domiciliary care. Control and ultimate elimination of malaria still constitute a major challenge, but the effects of a more enlightened outlook on leprosy are apparent in the recognition of the need for social rehabilitation of those cured.

Of the 9,923 Colonial students in the United Kingdom and the Irish Republic at the end of 1957, 1,298 held scholarships and 2,709 were at universities. Of the total, 3,360 were from West Africa and 3,096 from the West Indies; 867 were studying engineering, 745 medicine, 308 science, 228 economics, 89 agriculture and 69 dentistry. Tribute is again paid, here and in respect of information services, to the work of the British Council. It is estimated that 1,033,000 U.S. dollars will be spent on the United Nations Expanded Programme of Technical Assistance in the British territories in 1958 compared with 1,271,000 dollars in 1957. Under the Fulbright Agreement nine American teachers were posted to schools in Western Nigeria, St. Helena, Antigua, Grenada, Jamaica and Montserrat, and nine senior research workers attached to university and research institutions in East Africa, Northern Nigeria, Hong Kong, Jamaica and Trinidad, while two scientists continued research into the preservation of wild life in the game reserves of Uganda. Travel grants enabled lecturers from University College, Ibadan, the University College of the West Indies and the University of Malaya to visit the United States for research and to give lectures. An Overseas Visual Aid Centre has been established in London with the joint support of the Government and the Nuffield Foundation to further the use of visual and audio-visual aids in education.

SOLID STATE PHYSICS

CONFERENCE IN BRUSSELS

As part of the activities associated with the Brussels Universal Exhibition, a Conference on Solid State Physics and its applications to electronics and telecommunications was held in Brussels during June 2–7. The meeting had the patronage of the King of the Belgians and the support of the International Union of Pure and Applied Physics. It was regarded as appropriate because of the stress laid by many exhibitors on contemporary scientific achievements. After an introductory lecture by W. Shockley, the 750 participants from twenty-four countries divided up to listen to papers which were grouped in five parallel sessions throughout the six days of the conference.

It was inevitable that such a meeting would be dominated by discussions of the properties of semiconductors, their theory, and the main applications in transistors, phosphors and electroluminescence. There were also sessions on ferrites. Despite the extent of the field covered, its unity, so far as basic ideas are concerned, became very clear as the meeting progressed. This proved to be a stimulus to many participants, who regretted the large number of papers offered rather than the spread of topics.

The areas of activity in the field of pure semiconductors include equilibrium properties such as susceptibility measurements, transport phenomena, the study of barrier layers and surfaces, of noise, life-times and recombination, optical properties, the growth of, and imperfections in, single crystals, and the changes induced by irradiation. All these topics, and others on the more applied side, were discussed at this meeting, as they were at the last similarly international meeting at Garmisch in 1956 (see *Nature*, 198, 1156; 1956). A slight change of emphasis has, of course, occurred. For example, at Garmisch considerable interest was shown in the newly discovered phonon drag effect, which implies, for example, that long wave-length phonons exert a drag on the charge carriers, and contribute rather strongly to thermal conduction. Little was said about this effect in Brussels. On the other hand, the properties of electrons which are not in equilibrium with the lattice owing to the effects of an applied electric field—the so-called 'hot electrons'—received much more attention than they did at Garmisch, and this promises to remain an active field.

For example, J. Bok (École Normale Supérieure, Paris) reported attempts by thermionic emission experiments to obtain direct evidence of the temperature of hot electrons. S. H. Koenig (I. B. M. Watson Laboratories, Columbia University) emphasized again that the hot electron distribution function responds very rapidly (within less than 10^{-9} sec.) to changes in the applied field. In many aspects of these effects theory still lags behind experiment. This became particularly clear from a talk by R. Stratton (Metropolitan-Vickers Electrical Co., Manchester), who discussed theories of the dependence of electron mobilities on the electric field.

As the applied field is increased, the hole and electron temperature rise, and in due course breakdown occurs. In *p–n* junctions the breakdown is believed to be of the avalanche type. This was discussed for germanium by B. M. Wul (Lebedew Institute, Moscow). He showed that the coefficient of impact ionization for holes is about twice that for electrons. Recent work for silicon (Chynoweth, A. G., *Phys. Rev.*, 109, 1537; 1958) is of interest here for comparison. The properties of hot electrons may also be expected to affect the current–voltage relation of *p–n* junctions for high forward currents. This was discussed by A. K. Jonscher (General Electric Co., Wembley), the suggested form of the relation being $I^{1/2} = AV(V - B)$.

In this field of barrier-layer physics, attention was directed by several speakers to the measurement of the working temperature in the barrier (which has a pronounced effect on the properties of silicon and germanium rectifiers). Considerable interest was also shown in narrow germanium *p–n* junctions containing high concentrations (10^{18} to 10^{20} cm.$^{-3}$) of impurities. In such structures the Fermi-level can lie below the top of the valence band on one side, and above the bottom of the conduction band on the other side. This gives rise to stability against thermal shock, and to a forward current-voltage characteristic which exhibits negative resistance (for preliminary results, see Esaki, L. (Tokyo), *Phys. Rev.*, 109, 603; 1958). An incidental point of interest is that the direction of rectification is opposite to the usual one, and so is in agreement with that suggested in 1932 on the hypothesis of electron tunnelling.

It appears that semiconductor surfaces are being investigated increasingly by means of adsorption characteristics. The possibility of either mobile or localized adsorbed films of various kinds on germanium surfaces was envisaged by M. J. Sparnaay (Philips Research Laboratories, Eindhoven), and by H. Statz (Raytheon Co., Waltham, Mass.). Low-energy electron diffraction and work-function measurements were used by H. E. Farnsworth *et al.* (Brown University, Rhode Island) to study the structure and adsorption characteristics of clean germanium surfaces. He showed that surface atoms, displaced on a clean surface, appear to be restored to their normal positions by the presence of a chemisorbed oxygen monolayer. The effect of oxygen adsorption on the photoelectric sensitivity of bismuth films was discussed by R. Suhrmann (Hannover).

An interesting group of papers on silicon was submitted from the British Associated Electrical Industries group of companies. R. C. Newman and J. Wakefield (A.E.I. Laboratory, Aldermaston) pointed out the possibility of a connexion between the formation on silicon surfaces of etch pits on one hand and of silicon carbide on the other. The distribution of impurities in pulled silicon crystals was discussed, among other topics, in two papers (N. R. Howard ; P. Ransom, British Thomson-Houston Co., Rugby). H. F. Mataré (Sylvania Electric Products, Inc., Bayside, N.Y.) reported electrical experiments on bicrystals having known angles of misfit, and drew conclusions about the overlap of wave-functions of dangling bonds which occur at grain boundaries. Further information about these effects was expected at the meeting being held at Rochester, New York, at which a session is being devoted to grain boundaries and dislocations. An interesting aspect of crystal imperfections is their effect on mechanical damping. In silicon and germanium single crystals the damping usually shows two peaks when regarded as a function of temperature. The low-temperature peak at about two-thirds the melting point may perhaps be associated with the movement of dislocations. The high-temperature peak is probably connected with the motion of dissolved oxygen. A paper on these effects was read by P. D. Southgate (Mullard Laboratories, Salford).

Because of their applications to thermoelectric refrigeration a session was devoted to tellurides. The theory of remanent magnetization, important in connexion with magnetic recording tapes, was discussed by E. P. Wohlfarth (Imperial College of Science and Technology, London). Other applications which were considered included the use of impact ionization of impurities for low-temperature computing elements, applications of fluorescence to post office sorting problems, and several papers on transistor technology. As in the case of the earlier meeting at Garmisch, band calculations were discussed only incidentally. Impurity band conduction was mentioned somewhat more prominently—for example, in some speculations about the transition to metallic impurity band conductivity. The apparent absence of impurity band conduction down to 2° K. in some specimens of InSb was pointed out by E. H. Putley (Royal Radar Establishment, Malvern).

Other stimulating contributions, for example, in magneto-optics, are not mentioned here, since they are included in other conferences this summer. The proceedings of the Brussels meeting have been promised for the end of this year. Those of the 1956 Garmisch meeting are still expected.

P. T. Landsberg

STERIC EFFECTS IN CONJUGATED SYSTEMS

The consequences of steric interactions in organic molecules are of wide practical and theoretical interest to chemists, but the entire field of steric effects in organic chemistry is too vast to be covered in one conference. "Steric Effects in Conjugated Systems" was therefore chosen as the title for the Chemical Society symposium, held in Hull during July 15–17, because this topic is still of wide appeal to chemists and yet is sufficiently specialized to be treated in considerable detail by some fifteen papers, dealing with the study of steric effects by spectroscopic, kinetic, and other physical methods.

The introductory paper was read by Prof. E. E. Turner (Bedford College, London). He traced the chemical developments which led away from the Kaufler formula for diphenyl to the concept of a molecule comprised of two collinear benzene nuclei which will tend to be planar. This structure allowed an explanation of the optical isomerism of suitable diphenyls carrying four, three, two, or even one substituent in the sterically sensitive *ortho*-positions. This marked the discovery of molecular dissymmetry arising from restricted rotation about a bond—one of the most important steric effects which may arise in a conjugated system—and led to more recent work on 2 : 2′-bridged diphenyls. The conformational stabilities and molecular configurations for compounds containing two or more atoms in the bridge are now being studied by ultra-violet absorption spectroscopy.

Steric effects in diphenyl were also treated by Dr. G. H. Beaven (National Institute for Medical Research), who discussed the ultra-violet absorption spectra of pure alkyldiphenyls. While a 4-methyl substituent gives a red shift and an intensity increase of the conjugation band, 2-methyl substitution gives a blue shift and an intensity decrease. Further methyl substitution in the *ortho*-positions increases this effect, and the results are consistent with the hypothesis that progressive introduction of methyl groups into these positions gives progressive deviation from coplanarity and decrease in conjugation. Higher alkyl groups, unless branched, do not increase the steric effect, and the spectrum of 2 : 2′-dimethyldiphenyl suggests that the molecule has the *cis*-configuration already reported for 2 : 2′-dihalogenodiphenyls. The vapour-phase chromatography of these alkyldiphenyls was discussed by Dr. E. A. Johnson (National Institute for Medical Research), who has shown that the retention volumes for a single stationary phase depend on the position of the alkyl groups. Thus, 2-alkyldiphenyls have smaller retention volumes than the 3- or 4-isomers, presumably because the lower conjugation in the 2-isomer gives rise to less interaction with the stationary phase. The results confirm the conclusions reached from ultra-violet spectra relating conjugation to position and number of alkyl groups, and it has been possible to identify the peaks of a gas–liquid chromatogram of 21 isomeric tetramethyldiphenyls. Conjugation in 2 : 2′-bridged diphenyls and in halogenodiphenyls was also discussed in the light of the relative retention volumes for the compounds.

The influence of steric interactions upon the mesomorphic behaviour of 4-*p*-*n*-alkoxybenzylideneaminodiphenyls and 4 : 4′-di-(*p*-*n*-alkoxybenzylideneamino) diphenyls was discussed by Dr. G. W. Gray (University of Hull). A 2- or 2′-substituent in the diphenyl nucleus decreases the mesomorphic thermal stability more than a 3- or 3′-substituent. Clearly, twisting about the 1 : 1′-bond interferes with the molecular packing in the mesophases, and indeed increasing size of halogen increases the effect. A methyl group appears to have about the same steric effect as a chlorine, and 2 : 2′-disubstituted derivatives appear to adopt a *cis*-configuration. It is difficult to assess the configuration of the unsubstituted diphenyl ring system in the mesophases, but the results suggest that it may be planar.

Prof. C. A. Coulson (University of Oxford) described the use of molecular-orbital theory to explain the observed blue wave-length shifts in the ultra-violet spectra of diphenyls when the molecule is twisted about the 1 : 1′-bond. Reference was made to an alternative procedure developed by Longuet-Higgins and Murrell for such a system A–B (A and B may be groups such as phenyl, nitro-, etc.), and this was thought to be of promise for dealing with nitroanilines, where a full self-consistent-field molecular-orbital calculation would be complex. Relief of steric strain by displacement was then discussed by reference to the idealized case of a benzene ring folded through an angle about the 1 : 4-axis. The method of using mean resonance integrals was applied to this condition, which is similar to that occurring in the *paracyclo*phane series, and used to explain the observed bathochromic shifts in these compounds. The same method was used to deal with 3 : 4-benzphenanthrene which on 5- and 4′-methylation gives a progressive red shift which must be due to steric strain. The calculated effective resonance integrals for the mono- and di-methyl compounds agree excellently with those derived from spectra, and, moreover, the observed methyl affinities and the calculated free valences of the hydrocarbon agree well. The technique of using an average resonance integral is safest for such large polynuclear molecules where the strain is uniformly distributed throughout the molecule.

The contribution of Prof. M. J. S. Dewar (Queen Mary College, London) on the light absorption of cyanine dyes also concerned the direction of wave-length displacements arising from deviations from coplanarity. Hypsochromic displacements occur in the unsymmetrical cyanines, but the more unusual bathochromic shifts are observed in symmetrical cases. Prof. Dewar criticized explanations of these effects based on resonance theory, and applied molecular-orbital theory to the problem. While the strain of small distortions may be taken up by twisting about the central bonds in the dye, it is possible that large strains cause distortion of the whole molecule—buckling of rings—and this would lead to bathochromic shifts. Prof. Dewar considered that a more detailed treatment of this kind would be useful.

Steric effects in dyes again featured in the paper by Dr. C. C. Barker (University of Hull) on basic di- and tri-phenylmethane dyes. When the three main types of basic dye—Michler's hydrol blue, malachite green and crystal violet—are substituted, the molecular conformation and the electronic absorption spectra are usually modified, and Dr. Barker related the direction and extent of observed wave-length shifts to the steric and conjugative effects of the substituents. Alkyl derivatives of the three main types were fully discussed, and with malachite green the effects of numerous substituents in the phenyl ring were determined for comparison with the effects of substitution in the dimethylaminophenyl rings.

To the two classes of steric effect in ultra-violet absorption spectra proposed by Braude—steric interactions causing changes in (1) intensity only and (2) both wave-length and intensity—Prof. W. F. Forbes (Memorial University of Newfoundland) adds a third, covering steric interactions which so inhibit conjugation that the system absorbs as two entities. The mechanisms underlying the different types were discussed, although, in the absence of planar reference compounds, the identification of the type of effect may be difficult. Prof. Forbes illustrated the effect of both substituent size and nature of solvent upon the type of steric effect, and mentioned developments to which adoption of the classification may lead.

Dr. E. S. Waight (Imperial College of Science and Technology, London) concluded from measurements of the ultra-violet absorption spectra of conjugated carbonyl compounds at 20° and −196° that type I steric effects cannot be associated with transitions from non-planar ground-states to near planar excited states. From the infra-red and ultra-violet spectra of αβ-unsaturated carbonyl compounds, it is concluded that 2-methyl-1-acetyl*cyclo*hexane has an s-*cis*-structure, which is not planar. Using the ideas of Longuet-Higgins and Murrell on electronic transitions in the system C=C—C=O, it is thought that steric hindrance to planarity will produce Braude's type I effect when the transition is to an electron transfer state, and to a type II effect when the transition involves locally excited states.

Steric effects in monomethyl 1 : 2-benzanthracenes were discussed by Dr. G. Dallinga (Shell Laboratories, Amsterdam). The basicity constants and rates of H–D exchange for the twelve methyl isomers correspond strictly, but the observed basicities can be discussed in terms of the methyl group's inductive effect only when steric effects do not operate. Steric effects must therefore influence both the basicities and the rates of exchange for these isomers, and it is proposed that the structure for the transition state for the exchange resembles that of the conjugate acid. To explain the enhanced basicity of the 9-carbon atom, a steric repulsion is proposed between the hydrogens on the 9- and 1′-carbon atoms.

The influence of *ortho*-substituents upon the reactivities of groups in aromatic molecules has been extensively studied, since the Hammett equation is useful only in correlating reactivities in *meta*- or *para*-substituted systems, where there is no steric effect. Mr. A. C. Farthing and Mr. B. Nam (Imperial Chemical Industries, Ltd.) have derived a four-parameter, modified Hammett equation for *ortho*-substituted systems:

$$\Delta \log K = \sigma_S \rho_S + \sigma_E \rho_E$$

A graphical test ($\Delta \log K/\sigma_S$ against σ_E/σ_S) for forty-five reactions in the literature gives a correlation which is good enough to warrant statistical analysis and which suggests that the equation has some empirical validity.

In electrophilic aromatic substitution or side-chain reactions involving an electron-deficient centre, strong resonance interactions occur between the centre and the substituent. Such interactions are unimportant in the ionization of benzoic acids from which Hammett substituent constants are derived, and the constants cannot be used to treat the above reactions. Prof. H. C. Brown (Purdue University, Indiana) seeks to extend the Hammett treatment to these exceptional systems by obtaining substituent constants incorporating such resonance interactions from the rates of solvolysis of phenyldimethylcarbinyl chlorides. These electrophilic substituent constants have proved useful in quantitatively correlating directive effects in electrophilic aromatic substitution reactions, but a theoretical basis is required for the empirical correlations.

A review of steric effects in nucleophilic aromatic substitution by Prof. N. B. Chapman (University of Hull) covered both primary kinetic steric effects—steric retardation or acceleration of reactions—and secondary steric effects—steric inhibition of mesomerism. Examples of these effects, many from Prof. Chapman's work on nucleophilic aromatic substitution, were given. Although steric acceleration of a reaction is rarer than retardation, the effect is often large when it occurs, for example, in the Smiles rearrangement of 2-hydroxy-2′-nitrodiphenyl sulphone to 2-*o*-nitrophenoxybenzenesulphinic acid. The difficulties in reaching mechanistic interpretations of primary kinetic steric effects were discussed, and attention paid to the influence of the size of the attacking nucleophilic reagent.

Dr. B. M. Wepster (University of Delft) illustrated how the careful interpretation of electronic absorption spectra can lead to a better understanding of chemical data. Thus, the linear relationship between the conjugation band intensities in the ultra-violet spectra and the ΔpK_a values for the *p*-nitroanilines confirms that the inductive and mesomeric effects of the nitro-group operate almost equally in these molecules. The absorption spectra data for nuclear-alkylated anilines and N : N-dimethylanilines are used to interpret their relative base strengths, while a study of substitutional changes upon the relative base strengths of the nitrogens in 4-aminoazobenzene assists in interpreting the spectra of these compounds in acid solution. The negative inductive effect of the dimethylamino-group and the relative rate-constants for the alkaline deacylation of 4-nitro- and 2 : 6-dimethyl-4-nitro-acetanilide were also discussed.

Finally, Dr. J. W. Smith (Bedford College, London) discussed dipole moment evidence regarding steric effects in aromatic molecules. Factors which interfere with the coplanarity of a group with the aromatic ring diminish the mesomeric effect and are reflected in the dipole moment. Thus, in *ortho*-substituted nitrobenzenes and N : N-dimethylanilines, μ(obs.) is less than μ(calc.). In anilines, however, an *o*-methyl inhibits mesomerism slightly, while the slightly larger bromine does not. Yet, dipole moment evidence shows that bromine has the greater steric effect upon nitro-, formyl, and acetyl groups. It is inferred, therefore, that the characteristics of the group are important in determining repulsions, and that bromine may have a smaller effective radius with respect to approach by hydrogen than by oxygen, and that the reverse applies to the methyl group.

G. W. Gray

OVERSEAS INFORMATION SERVICES

Speaking in a debate on the Overseas Information Services in the House of Lords on July 9, Lord Adrian stressed the importance of medical and scientific contacts in Commonwealth relations. Fellowships for advanced study and research to able young men and women, if properly used, were the best kind of information service we could give, and Lord Adrian thought we could well spend much more than the present £1 million on such contacts. He referred in particular to the Commonwealth Fund Fellowships, to the British Council's scholarships for postgraduate study and those of the Nuffield and Leverhulme Foundations. Other tributes to the work of the British Council were paid by Viscount Massereene and Ferrard, who, in opening the debate, also referred particularly to the importance of telling the world of our scientific and industrial achievements, Lord Birdwood, Lord Ogmore and by the Earl of Home and the Earl of Gosforth, who spoke for the Government. The Earl of Home assured the House that the Government wishes to strengthen and render more efficient all the information services, and stressed the importance of concentrating expenditure where it was likely to be most effective. In a notable tribute to the British Council he referred to the expansion in the number of Commonwealth students in Britain from between 2,000 and 3,000 in 1946 to 35,000 in 1957, when 11,000 were at universities. He thought, however, that the independent committee of advisers suggested by Lord Birdwood was unlikely to add much to the knowledge of the chief information officers of the Overseas Departments ; but he agreed to discuss the proposal and also that of the Drogheda report for a permanent advisory committee with the Chancellor of the Duchy of Lancaster later.

Lord Croft raised the question of the export of British books, particularly scientific and technical text-books, which in countries like India, Pakistan, Burma and Ceylon had largely been displaced by United States text-books, partly in consequence of the aid and information programmes of the American Government. This situation seriously handicapped the sale of British products overseas, and because the distribution of British books and periodicals created a favourable climate for such sales he suggested the Government might, particularly in areas where competition is heaviest, give aid to all central libraries, university libraries and education centres abroad in the selection of British books on particular subjects. For this purpose an initial expenditure of £40,000 and an annual expenditure of £8,000 should service some 400 centres. He suggested also the organization of a limited number of exhibitions of books in areas not served by the British Council and the establishment of a Joint Standing Committee of the British Council and the Central Office of Information on one side, and a voluntary organization of the National Book League and the Publishers' Association on the other, to consider the whole problem. Lord Crook added that about 100,000 copies of books from the United States were being distributed at cut prices and that besides spending 5 million dollars on the translation, publication and distribution of books abroad, the United States, under a low-cost publication programme, had in 1957 launched 4·5 million copies of books in 185 editions and 21 languages. He also pointed out that although we invented the British Book Export Scheme, we did not use it, and because of the Treasury's attitude there were in consequence no schemes for dealing with the position in Pakistan, in Israel and in Turkey. Even with the help of the Colombo Plan many Pakistan universities and libraries were unable to obtain the British books they need, and their science faculties had lacked all specialist periodicals over the past ten years; there was an unsatisfied annual demand there for £50,000 worth of British books and £15,000 worth of periodicals. The Earl of Gosforth, in concluding the debate, made no specific comment on this situation, but promised that all suggestions made in the debate would be carefully considered.

HOSPITAL SERVICES IN GREAT BRITAIN

THE debate on the hospital services in Britain, in the House of Lords on July 2, opened by Lord Nathan, was noteworthy both for the review of the first ten years operation of the National Health Service and for the stress which was laid upon medical research by Lord Nathan himself and other speakers. Lord Nathan said that while there had been no increase in the number of teaching hospitals, the number of beds had increased from 26,000 to nearly 28,000, and in the non-teaching hospitals from 475,000 to 481,000; the bed-occupancy had remained at just over 80 per cent in the teaching hospitals and increased from 79 to 83 per cent in the non-teaching hospitals. The medical and dental staff over the whole country had increased by about 30 per cent, and in the teaching hospitals the number of nurses had increased by 20 per cent, but only by 10 per cent in the non-teaching hospitals, where the number of out-patients was now about 18·5 million a year, compared with 9·5 million in the teaching hospitals in 1956 (an increase of 2 million on 1949). Lord Nathan referred to the increase in voluntary service in the hospitals, to the increased space demanded by new developments in surgery and treatment and, finally, to the extreme importance of research, including the value of sending staff abroad to study methods used elsewhere. We could not expect to retain in our hospitals or in Britain men of the right quality unless we provided them not merely with adequate remuneration but, even more important, with the opportunities for developing their powers and their careers within their profession to the utmost. As regards costs, Lord Nathan said that the Guillebrand Committee found that capital expenditure in 1952–53 was only one-third what it had been in 1938–39, and he added that running costs for 1958–59 were estimated at just under £400 million, an increase of 4 per cent on 1957–58.

Other points emphasized in the debate were the shortage of accommodation for elderly persons, the vital importance in the teaching hospitals of the personal influence of the teacher on the student. Lord Evans stressed the dependence of the standard of of our teaching hospitals upon this personal contact between teacher and student. He also suggested that the hospitals should be encouraged to seek additional sources of finance. Lord Moran referred to the importance of the redistribution and the increase in number of consultants, so that there were now available in almost every part of the country first-rate specialists in every branch of medicine, and he supported Sir George Pickering's suggestion that every drug in the Pharmacopœia should be investigated to see when it is necessary as the only way to reduce the drug bill of £74 million a year. Lord Addison said a brake might be placed upon research generally in teaching hospital groups, because of the difficulty in handing over to the Exchequer vote methods resulting from research activities after they had taken their place in normal clinical procedure, and suggested that some more frequent method of assessing the stages to which research had developed might be advantageous. Reference was also made to the great advance in the treatment of mental diseases, but Lord Pakenham thought that an expenditure of only 2 per cent of its funds by the Medical Research Council on research into mental health was inadequate.

In his reply for the Government, Lord Strathclyde pointed out that, since the Guillebrand report, capital expenditure had considerably increased and was now about £23 million compared with £12 million in 1952–53. He states that the Government fully realized the importance of research, and said that it fully accepted the value of travelling scholarships and that hospital boards had been given very considerable discretion to grant study leave. In 1948–57, £18 million out of a capital expenditure of £70 million had been spent on mental hospitals, and the percentage had risen from 23·9 in 1948–56 to 32·7 in 1956–57. The Government was also fully alive to the potentialities in the application of work study.

TRANSPLANTATION OF THE FOREBRAIN REGION IN BIRD EMBRYOS BEFORE THE ESTABLISHMENT OF A CIRCULATION

Homoplastic Transplants

IN a recent publication one of us described a technique by which the forebrain region of chicken embryos at the stage of development prior to the establishment of a circulation can be transplanted to hosts of a corresponding stage[1]. Successful auto- and inter-breed homo-transplants have been obtained. Some of the grafted embryos, including the graft, continued to develop in a fairly normal way up to the time of hatching. Further work with the forebrain grafts showed that some of the grafted embryos are capable, with very little assistance, of freeing themselves from the shell, and living thereafter for considerable periods. So far, five such animals have been obtained. Of these, one was an autografted Rhode Island Red, three were homografted Rhode Island Reds and one was a Rhode Island Red on to which the forebrain of a Barred Rock Black embryo was grafted. The autografted chick was killed 77 hr. after hatching. One homografted chick died 30 hr., another 36 hr. and the third 55 days after

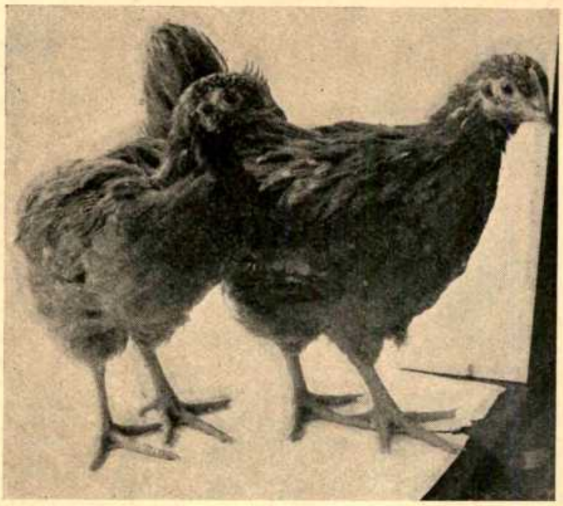

Fig. 1. Graft, Barred Rock Black; host, Rhode Island Red. Left, grafted bird; right, control. When photographed, this bird was 45 days old. The host is a female, the graft was probably taken from a male. Note deep toothed comb and absence of tail feathers

hatching. The Rhode Island Red to which the Barred Rock was homo-grafted is 60 days old and still alive; so far, its rate of growth has been nearly normal (Fig. 1).

One of the most frequently observed phenomena in such grafted chickens is a retardation in development, accompanied by lowered viability. In some embryonic chickens the incubation period was prolonged by 1–5 days; such birds failed to hatch. Anomalies in the appearance and in the distribution of pigment in inter-breed 'crosses' were also common.

In the chicks that hatched, retarded growth of the feathers and their anomalous distribution over certain regions of the body were also observed. In the two birds that survived for longer periods, especially in one of them, the rate of growth was less than that of normal controls. On the other hand, both of them had perfect control over their feeding reflexes; their movements were, or are, well coordinated, and the sight and hearing appeared to be perfectly normal. The functioning of the vocal organ was also normal. The autopsied embryos that have been examined so far had apparently normal pituitary glands. The hatched autografted chick was the only animal in which the pituitary gland was not found.

Crude operational technique may result in very imperfect healing between the two cut surfaces of the brain mass and, without unduly affecting the eyes and the mouth parts, give rise to profound disturbances in the anatomy of this organ. What type of healing is obtained with embryos that hatch, and how far the general state of the organism is affected by it, only further work will show.

Heteroplastic Transplants

BY the use of a technique originally applied to transplants of the forebrain region in chicken embryos[1], reciprocal transplants of the forebrain region between chicken and duck embryos were attempted. Figs. 1 and 2, of a chicken forebrain graft to a duck, and of a duck graft to a chicken, respectively, illustrate the possibilities of the growth and development of grafts between embryonic hosts belonging to two different species of birds. We have not, as yet, analysed closely the processes taking place in the course of development of these grafted embryos, but in their essentials they are similar to those observed in homografted ones. The establishment of vascular connexions between the host and the graft is somewhat delayed in comparison with that in homografted embryos and this may seriously affect further differentiation and growth both of the graft and the host. In spite of this, normal-looking eyes developed in both chicken-to-duck and duck-to-chicken grafts, and an almost normal upper beak in some chicken-to-duck transplants (Fig. 1). A fairly normal but retarded upper bill was formed in a duck-to-chicken transplant (Fig. 2).

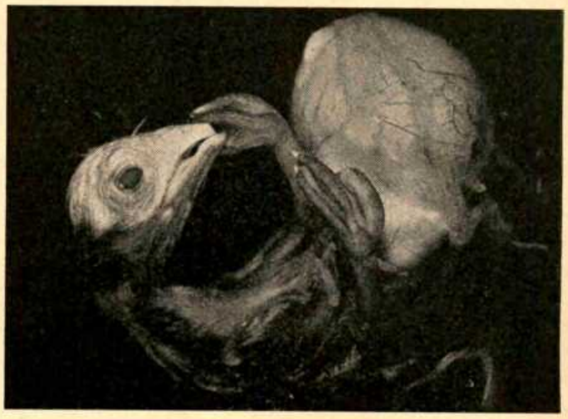

Fig. 1. Graft, Rhode Island Red; host, Khaki Campbell. Embryo removed from the shell on the 22nd day of incubation. The mandible has developed from the host tissues, and the upper beak from the graft

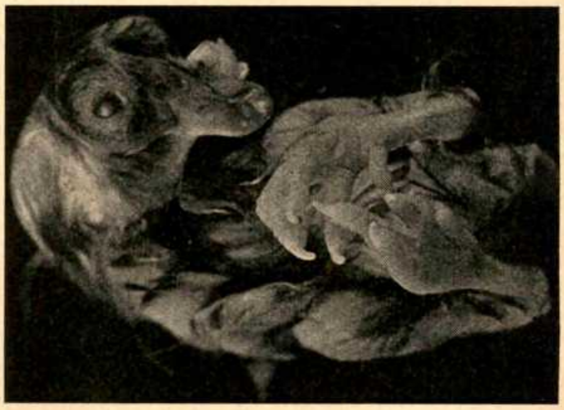

Fig. 2. Graft, Khaki Campbell; host, Rhode Island Red. Embryo removed from the shell after 23 days of incubation. The right eye and the upper bill are well developed; the left maxilla is defective

MACMILLAN BOOKS

Atlas of the Sky

VINCENT DE CALLATAŸ

Translated and with a Foreword by Sir Harold Spencer Jones, former Astronomer Royal. This unique atlas, containing 72 pages of text and 36 plates, has been planned for use by amateurs of astronomy. All the stars represented are visible to the naked eye, in both northern and southern hemispheres. 65*s*

Looking at Chromosomes

JOHN McLEISH and BRIAN SNOAD

The aim of this book is to demonstrate, by means of a continuous series of photographs and illustrations, how cells and the hereditary substances they contain behave during the growth of a living organism, how the cells which function in reproduction come to be formed and, finally, how the hereditary substances are passed on from parents to offspring. Of great value to students with some knowledge of biology.

48 *plates and many diagrams* 16*s*

The Economics of International Migration

EDITED BY *BRINLEY THOMAS*

Trends in international migration have been profoundly changed in the last thirty years by the American Restriction Act of 1924, the great depression of the early 1930's and the Second World War. Twenty-four papers on the subject by leading experts, and a record of the discussions of the seventh conference of the International Economic Association. 45*s*

Modern Science and the Nature of Life

WILLIAM S. BECK

Assistant Professor of Medicine, Harvard
Chief of Haematology Research, Massachusetts General Hospital

'Dr. Beck has written an excellent and enthusiastic account of the present position of biological science and sketched its relation to other branches of scientific and philosophical thought.'—*Sunday Times.* 15*s*

MACMILLAN BOOKS

The Man-made Fibres Industry

R. ROBSON AUTHOR OF *The Cotton Industry in Britain*

The first book to tell of the development and structure of the industry, its economic and scientific basis, in England and overseas. 'Compactly written . . . to the point and right up-to-date. It can be thoroughly recommended to anyone who is confused by the complexity of the situation within the man-made fibre industry in which new fibres are emerging daily.'—*Skinner's Silk and Rayon Record.* 21*s*

An Atlas of Airborne Pollen Grains

H. A. HYDE and K. F. ADAMS

This atlas is intended primarily as an aid to the identification of pollen grains in the fresh condition. The ninety-two species described are those which can be observed at a magnification of about 1,000 diameters. The book should be of value in studies of airborne pollen in general and in relation to hayfever, and, to a lesser degree, the pollen loads of bees, and pollen in honey and in peat. *Illustrated* 36*s*

Textbook of Economic Analysis

EDWARD NEVIN

An introduction to the groundwork of contemporary economic and monetary theory. Assuming no previous knowledge on the part of the reader, it sets out to explain the nature and scope of economic analysis, and then proceeds to an exposition of the modern theories of demand, supply, value and income distribution. Finally, the book deals with the issues arising from international transactions. 'With this book Dr. Nevin will earn the gratitude of many teachers, to say nothing of their students.'—*Accountancy.* *With diagrams* 18*s*

Science and its Background

H. D. ANTHONY

The third edition of this book, which includes a chapter on the International Geophysical Year, gives something of the story of science, together with the background of history in which that story is set. 'An admirable introduction . . . This pioneer work should be in the hands of all students of the subject.'—*Science Progress.* 20*s*

ROBLEY C. WILLIAMS

IT IS INTENDED THAT the field covered by the new *Journal of Molecular Biology* will include the nature, production, and replication of biological structure at the molecular level, and its relation to function; and related topics:

- subcellular organization
- molecular genetics
- fine structure and replication of viruses
- molecular structure of muscle, nerve, and other tissues
- structure of proteins, nucleic acids, carbohydrates, lipids, and other biological macromolecules and their synthetic analogues. as investigated by X-rays, light absorption and other methods
- problems of intra- and inter-molecular energy transfer

Beside the usual type of original paper, *short* invited or contributed review articles on restricted fields of current interest will be included. Letters to the Editors which may be preliminary reports demanding quick publication or perhaps informed speculations which do not fit the normal framework of a published paper, and book reviews, are also eligible for publication. When refereeing does not entail serious revision, publication of manuscripts can be planned within four months from receipt for papers and two months from receipt for Letters to the Editors.

Papers will normally be published in English, and should be accompanied by a summary not exceeding 300 words. Manuscripts in French or German will, however, also be accepted, but should then be accompanied by an extended summary, in English, of up to 1,000 words.

Manuscripts should be sent to the Editor-in-Chief, Dr. J. C. Kendrew, Peterhouse, Cambridge, England, or to any member of the Editorial Board.

CAMBRIDGE BOOKS

Evolution by Natural Selection

CHARLES DARWIN & A. R. WALLACE

A centenary commemorative volume containing the Darwin-Wallace papers of 1858 *On the Tendency of Species to form Varieties*, together with Darwin's earlier work: the *Sketch* of 1842 and the *Essay* of 1844. A foreword by Sir Gavin de Beer traces the history of evolutionary theory and considers modern attitudes to Natural Selection. 25*s. net*

Scientific Papers, I

SIR GEOFFREY INGRAM TAYLOR

The first of four volumes, edited by Dr G. K. Batchelor, contains all Sir Geoffrey Taylor's papers on the mechanics of solids, written between 1917 and 1955. Some of them are made generally available for the first time. The book includes his famous work on the dislocation theory and studies of plasticity, elasticity and the properties of metals. 604 *pages;* 18 *plates,* 252 *figures,* 90 *tables.* 75*s. net*

Nuclear Scattering

K. B. MATHER & P. SWAN

Much information on nuclear forces has been derived from a study of nuclear scattering. This book gives a clear account of the physics of nuclear scattering, including experimental techniques, significant experimental results and interpretation in terms of nuclear forces and nuclear structure. Of interest to all nuclear physicists, practical and theoretical. CAMBRIDGE MONOGRAPHS ON PHYSICS. 80*s. net*

The Structure of British Industry

EDITED BY DUNCAN BURN

A survey in two volumes of the organization and functioning of the principal British industries, giving the number, size, scope and inter-relationships of the firms in each industry. The effect of structure on economic performance, adaptability, degree of monopoly, and other topics are discussed. New industries are given special attention. An Economic and Social Study published for the National Institute of Economic and Social Research. *Volume I,* 45*s. net; Volume II, ready September,* 50*s. net*

CAMBRIDGE UNIVERSITY PRESS

Matrix Theory for Physicists

J. HEADING, M.A., Ph.D.

This book arises in part from ancillary mathematics lectures given to third year students reading for the internal special physics degree of the University of London in the approach to abstract algebra. The first two chapters contain the basic mathematical theory. Various types of matrix are defined, together with the fundamental operations associated with matrices. Cartesian tensors, in so far as they can be expressed in matrix notation, are also defined. The subject of characteristic roots and vectors is treated in detail, together with its mathematical applications. In the following five chapters, the theory is applied to the subjects of three-dimensional geometry, dynamics, electromagnetic theory, special theory of relativity, and quantum mechanics. It is naturally assumed that the reader is acquainted with the physical basis of the subjects discussed. The object of these chapters is not merely to cast the usual theory into compact matrix form, but to show how the theory may be developed in a systematic manner using matrix language *ab initio*. Each of these five chapters is almost self-contained, and on this account a consecutive reading of the book is not necessary. Having mastered the book, the reader should be in a position to understand most research papers employing matrix theory, and to read something of the more abstract and numerical sides of the theory found in texts and papers intended primarily for mathematical specialists.

With Diagrams 35*s. net*

Special Theory of Relativity

G. STEPHENSON, Ph.D., D.I.C.
and C. W. KILMINSTER

The theory is developed entirely in terms of the three-dimensional vector analysis.

It contains a large number of applications of interest to the research physicist and electrical engineer, including high-energy particle accelerators, classical meson theory, particle decay schemes, the Dirac wave equation, relativistic hydrodynamics, de Broglie waves, the relativistic Child-Langmuir law and many other topics. A detailed account is also given of the historical development of the subject and the relevant experimental work.

It is a complete and recent account of the subject for a wide circle of scientists without making heavy demands on their mathematical ability.

Tea (Tropical Agricultural Series)

T. EDEN, D.Sc., F.R.I.C.

This book gives a descriptive account of the various stages of tea cultivation and manufacture, discussing the fundamental agricultural and technological principles of the existing industry so that they may have relevance wherever tea cultivation is carried out.

INTERSCIENCE PUBLISHERS

Some recent Publications :

ADVANCES IN PETROLEUM CHEMISTRY AND REFINING (Volume 1)
Edited by K. A. Kobe *and* J. J. McKetta. 103/-
The first of a series to be published annually.

COLORIMETRIC DETERMINATION OF NONMETALS (CHEMICAL ANALYSIS Volume 8)
Edited by D. F. Boltz. 65/-
One of the most convenient of sensitive methods for trace analysis.

THE EFFECTS OF IONIZING RADIATION ON NATURAL AND SYNTHETIC HIGH POLYMERS
By F. A. Bovey. 60/-
The first volume in a new series in polymer science entitled Polymer Reviews.

ENCYCLOPEDIA OF CHEMICAL TECHNOLOGY : First Supplement
Edited by R. E. Kirk *and* D. F. Othmer. 175/-
Covers subjects in which recent advances have been particularly striking.

FILM FORMATION, FILM PROPERTIES, FILM DETERIORATION
Edited by C. R. Bragdon. 75/-
Studies of drying oils.

INDUSTRIAL HYGIENE AND TOXICOLOGY : Volume 1, General Principles
Edited by F. A. Patty. Volume 1. 132/-
Second revised edition, in three volumes.

ORGANIC SYNTHESIS WITH ISOTOPES (Part 1)
By A. Murray, III *and* D. L. Williams. 190/-
Part 1 : Compounds and Isotopic Carbon.

SURFACE ACTIVE AGENTS AND DETERGENTS (Volume 2)
By A. M. Schwartz, J. W. Perry *and* J. Berch. 132/-
Supplements Volume 1 : Surface Active Agents, Their Chemistry and Technology.

RESEARCH MANAGEMENT (Volume 1—1958)
A new quarterly journal which deals with questions of a general nature common to all kinds of industrial research. (*Published jointly with the U.S. Industrial Research Institute.*)
Annual Subscription, including postage, 60/-

CRYSTAL STRUCTURES (Supplement 3)
By R. W. G. Wyckoff 150/-
Now nearing completion.

DRYCLEANING : Technology and Theory
Edited by A. R. Martin *and* G. P. Fulton. 45/-

THE GYROSCOPE : Theory and Applications
By J. B. Scarborough. 46/-
The mathematical and mechanical aspects.

HOW TO MAKE A TELESCOPE
By J. Texereau. 25/-
Translated and adapted from the French.

INFORMATION RESOURCES
By J. H. Shera, A. Kent *and* J. W. Perry. 40/-
A challenge to American Science and Industry.

METHODS OF BIOCHEMICAL ANALYSIS (Volume 6)
Edited by D. Glick. 68/-
Another volume in this excellent series.

SCIENTIFIC GLASSBLOWING
By E. L. Wheeler. 75/-
Includes coating of glass with metal films, etc.

A COMPLETE CATALOGUE of technical books published and distributed by Interscience Publishers Ltd., is available on request.

DOVER BOOKS THE OUTSTANDING PAPERBACK SERIES

The following is a selection of some of the books available in the Dover reprint editions. All volumes are stitched as in cloth bound books so that pages do not become loose and fall out or the spines break. They are printed on good-quality paper and are paper-bound in attractive covers.

CALCULUS REFRESHER FOR TECHNICAL MEN. A. A. **Klaf.** 431 pages. Illustrated. 16s.

TRIGONOMETRY REFRESHER FOR TECHNICAL MEN. A. A. **Klaf.** 629 pages. Illustrated. 16s.

Both these titles use the question and answer method as a means of improving a working knowledge of the subjects. They give applications to mechanical, civil, hydraulic, electrical, aeronautical and other fields of engineering.

ATOMIC SPECTRA AND ATOMIC STRUCTURE. **G. Herzberg.** 257 pages. 16s.

THE ELECTROMAGNETIC FIELD. **M. Mason and W. Weaver.** 390 pages. Illustrated. 16s.

APPLICATIONS OF TENSOR ANALYSIS. **A. J. McConnell.** Formerly entitled "Applications of the Absolute Differential Calculus." 318 pages. Illustrated. 15s.

PHYSICAL PRINCIPLES OF THE QUANTUM THEORY. **W. Heisenberg.** 184 pages. 10s.

FUNDAMENTAL OF HYDRO- AND AERO-MECHANICS. Based on lectures of **L. Prandtl,** by **O. G. Tietjens.** Translated by **L. Rosenhead.** 270 pages. Illustrated. 15s.

APPLIED HYDRO- AND AEROMECHANICS. Based on lectures of **L. Prandtl,** by **O. G. Tietjens.** Translated by **J. P. den Hartog.** 311 pages. Illustrated. 15s.

THE ADVANCED PART OF A TREATISE ON THE DYNAMICS OF A SYSTEM OF RIGID BODIES (Being Part II of a Treatise on the whole Subject). **E. J. Routh.** 6th edition. 484 pages. Illustrated. 21s.

AN INTRODUCTION TO RELAXATION METHODS. **F. S. Shaw.** An introduction to the use of relaxation methods for the solution of differential equations, which describes most of the manipulative resources that have been found of value. 396 pages. Illustrated. 20s.

PARTIAL DIFFERENTIAL EQUATIONS OF MATHEMATICAL PHYSICS. **A. G. Webster.** 440 pages. 16s.

INTRO. TO STUDY OF STELLAR STRUCTURE. **S. Chandrasekhar.** Unabridged modern classic by a foremost astro-physicist. 509 pages. 22s.

APPLIED OPTICS AND OPTICAL DESIGN. **A. Conrady.** As a practical guide, has no rival. 150 illustrations. 528 pages. 24s.

FOUNDATIONS OF SCIENCE. The Philosophy of Theory and Experiment. **N. R. Campbell.** 565 pages. 24s.

FOUNDATIONS OF PHYSICS. **Lindsay and Margenau.** 1st-rate coverage of ideas and methodology of physics. 577 pages. 20s.

101 PUZZLES IN THOUGHT & LOGIC. **C. Wylie.** ENTIRELY NEW! No knowledge of maths needed to solve these entertaining problems; only ability to reason. 128 pages. 8s.

PHILOSOPHY OF SPACE AND TIME. **Hans Reichenbach.** 1st English translation of this famous work covering modern philosophy of science, relativity, etc. 320 pages. 16s.

HIGHER MATHEMATICS FOR STUDENTS OF CHEMISTRY AND PHYSICS. **J. Mellor.** Practical book for students; renowned for clear, practical exposition, based mostly on laboratory situations. Integral, differential calculus, etc. 662 pages. 16s.

THEORY OF FUNCTIONS OF A REAL VARIABLE & THEORY OF FOURIER SERIES. **E. Hobson.** Best intro. to sets, aspects of functions; more thorough than more modern works. Two vol. set. Total 1,591 pages. Each vol. 24s.

GEOGRAPHICAL ESSAYS. **W. M. Davis.** Contains 26 of Davis's most important papers. They cover the theory of geography, methods of advanced teaching, descriptions of various areas and analyses of land-shaping processes. 777 pages. 24s.

PSYCHOLOGY OF INVENTION IN MATHEMATICAL FIELD. **J. Hadamard.** Where ideas come from, role of unconscious, Einstein's method, etc. 158 pages. 10s.

THE EVOLUTION OF THE IGNEOUS ROCKS. **N. L. Bowen.** An essential reference book. 334 pages. 15s.

BRIDGES & THEIR BUILDERS. **D. Steinman and S. Watson.** World's foremost engineer covers bridge science from earliest times to present. Rev. ed. 418 pages. 16s.

TREATISE ON PLANE & ADVANCED TRIGONOMETRY. **E. Hobson.** Ranges beyond usual texts into theory of infinite series, etc. 405 pages. 16s.

HOW TO CALCULATE QUICKLY. **J. Sticker.** Tried, true method, over 9,000 problems, answers, to develop number sense. 256 pages. 8s.

MATHEMATICAL PUZZLES FOR BEGINNERS & ENTHUSIASTS. **G. Mott-Smith.** 188 puzzles of most interesting sort, detailed solutions. 248 pages. 8s.

MATHEMATICAL EXCURSIONS. **H. Merrill.** 90 puzzles, hundreds of short-cuts not generally known. 145 pages. 8s.

THE TAYLOR SERIES, AN INTRODUCTION TO THEORY OF FUNCTIONS OF A COMPLEX VARIABLE. **P. Dienes.** Full, detailed, thorough; only calculus needed. 186 examples. 567 pages. 22s.

Write for complete catalogue to: **CONSTABLE** **10 ORANGE STREET LONDON, W.C.2**

TAYLOR & FRANCIS INTERNATIONAL JOURNALS

1959 Publications in Preparation

INTERNATIONAL JOURNAL OF RADIATION BIOLOGY

and related studies in Physics, Chemistry and Medicine

Editor:
W. M. DALE, M.D., D.Sc.
Assistant Editor:
JOHN WAKEFIELD, B.A., F.Z.S.
Editorial Board:
Charlotte Auerbach, *U.K.*; D. K. van Bekkum, *Holland*; A. A. Buzzatti-Traverso, *Italy*; F. Devik, *Norway*; J. Firket, *Belgium*; M. Haissinsky, *France*; A. Hollaender, *U.S.A.*; B. F. Kaufmann, *U.S.A.*; G. Klein, *Sweden*; H. Langendorff, *Germany*; M. Magat, *France*; N. Miller † *U.K.*; E. Paterson, *U.K.*; H. Ulrich, *Switzerland*; M. Westergaard, *Denmark*.

AT present the results of research in radiation biology are published in a number of different journals. The ever-widening scope of this research has accentuated the need for an international journal to collect together relevant papers and provide additional facilities for publication.

The new Journal will publish original articles, critical reviews and reports of symposia dealing with experimental and theoretical work on the biological effects of ionizing radiations. The physical and chemical steps which lead to the biological end-effects will, of course, fall within its scope. There will also be a place for papers on clinical work, provided that they bear on the basic mechanisms of the action of radiations.

In addition to papers on these general subjects, the journal will publish work on methods and the use of instruments for radiation research ; in particular, dosimetry if it concerns biological problems directly ; relevant chemical techniques, including those which involve the use of radioactive isotopes ; and chemical agents which produce effects resembling those of radiation.

The Editorial Board will welcome contributions from all countries. Papers in English, French or German will be published, with summaries in all three languages.

There will be four issues of the journal per volume.

Price per part £1 0s. 0d. plus postage
Subscription per volume (4 issues) £3 15s. 0d. post free, payable in advance

Orders originating in U.S.A. and Canada should be sent to the Academic Press Inc., 111 Fifth Avenue, New York 3, N.Y., U.S.A.

OPTICA ACTA

an International Journal of Optics

Editors:
English Editor: C. G. Wynne. *French Editor:* A. Maréchal. *German Editor:* G. Franke.
Editorial Board:
J. M. Otero Y Navascues, *Madrid*; R. W. Ditchburn, *Reading*; A. Arnulf, *Paris*; A. Biot, *Gand*; J. Cabannes, *Paris*; P. Fleury, *Paris*; F. Gabler, *Vienna*; G. Hansen, *Oberkochen*; E. Ingelstam, *Stockholm*; H. Korte, *Braunschweig*; W. S. Stiles, *London*; G. Toraldo DI Francia, *Florence*; A. C. S. van Heel, *Delft*

From January 1959, *Optica Acta*, the leading journal in its field in Europe, is to be published by Taylor & Francis Ltd. The Journal will continue to publish papers on optical phenomena and the general theory of optics, optics of the eye and the properties of vision photometry, colorimetry and the scientific aspects of photography of optical interest. Papers on spectroscopic optics, instrumental optics, light sources and light sensitive receivers as well as those in the field of metrology all come within its purview, which will not be limited to the visible region of the spectrum. Papers and critical reviews will be published in English, French or German with summaries in all three languages.

Price per part £1 0s. 0d. plus postage
Subscription price per volume (4 parts) £3 15s. 0d. post free

BRITISH ASSOCIATION MEETING IN GLASGOW

SCIENCE AND BUSINESS: A BALANCED PARTNERSHIP*

By Sir ALEXANDER FLECK, K.B.E., F.R.S.
President of the British Association

THE British Association has returned to Glasgow after the passage of some thirty years. The president on that last occasion was Sir William Bragg, and it is good to know that his son maintains a fine scientific tradition as director of the Royal Institution and of the Davy Faraday Laboratory. We are glad to have this opportunity in the course of our scientific deliberations to see something of the progress that has taken place in Glasgow and its region since then. In 1928 the Scottish Lowlands were reasonably prosperous : they had not yet entered the lean and hungry years of industrial depression when men's labours ground to a standstill and unemployment paralysed much initiative. As is well known, the depression lasted until early 1939, to be followed by the trials of war, death and destruction from the air, and all the while the deluding sense of prosperity that war brings. Since the end of the War, Glasgow has seen great industrial activity, though there are again threatening clouds in the sky.

But Glasgow's story goes back far beyond the fluctuating fortunes of the past thirty years. The little Cathedral town which emerged from the sixth century settlement beside the Molendinar has become one of the greatest cities of the Commonwealth. The shallow, unpolluted Clyde has become the deep-dredged channel which has carried the world's largest ships, a source of trade and prosperity to Scotland.

We of the British Association pay tribute to the creative scientific thought of the citizens of Glasgow which has enriched the world : first, Adam Smith, original economic thinker, who stood between the two storms that broke over Scotland—the Reformation and the Industrial Revolution ; then the chemist, Joseph Black, whose work on the theory of heat helped to inspire James Watt, himself prime mover of the Industrial Revolution. Lister, a past president of the Association, came to revolutionize surgical methods ; Kelvin, another president, established principles of thermodynamics and electricity, and so 'put a girdle round about the earth'. In our own time, Soddy's work on atoms helped to name the new atomic age, presently so much in our minds.

These are some of the men who towered above their contemporaries and their century, men whose names make the British Association proud to renew its contact with the City of Glasgow and recall the debt that the world owes to it.

We hope that the citizens of Glasgow will always, in the same inspiring tradition, promote the advancement of science, technology and philosophical thought.

I am very sensible of the honour that the Council of the British Association has done me by electing me president for this Glasgow meeting and so enabling me to come back with the Association to the place in which I first saw the light of day just on the south bank of the Clyde. The surroundings there were all of trade and business, so I trust I can with appropriateness express some general thoughts on business and science and the need for a proper balance between them. This subject is very different from those chosen by most of the presidents who have addressed this Association in the 127 years of its existence : they have spoken from the wealth of their expert knowledge of some science to which they have added great lustre. There is no science with which I, on the other hand, can claim the intimate acquaintance of a practising scientist. It is many years since I worked at a laboratory bench and experienced the excitement of anticipation all research workers feel as a well-planned experiment approaches its conclusion. That phase passed into one in which I supervised and directed others to do such work, and later that also was left behind under the pressures of full-time administration. The result of all this is that I am no specialist in any branch of science. Rather, I approach my task here as a sort of common man of science, who, lacking the detailed knowledge of the specialist, has at least an understanding of the framework within which scientific thought evolves.

All the same, it may be felt that in my dual capacity as president of the Association and as an administrator, I run the risk of finding myself a business man among scientists and a scientist, even if only a lapsed scientist, among businessmen. Perhaps I may remind you of a remark ascribed to Talleyrand : "War is much too serious a thing to be left to military men". I have the impression that the same sentiment may apply both to the conduct of business and to the advancement of science. The risk of being neither pre-eminently scientist nor pre-eminently businessman may be counterbalanced by advantages that come from a non-specialist approach to science and business. I hope to show why such an approach may be particularly appropriate to the needs of the moment.

Science

In a population which depends so much on science, it is sad to think how few people clearly understand what it is all about. It is an approach to an understanding of the universe along a broad highway of organized knowledge firmly founded on observation and experiment embedded in a matrix of theory. It is a highway which is constantly being widened and extended and repaired. We are building it because we think that, by and large, it is a good road for mankind to travel, and that it is leading him away from ignorance and wretchedness towards a fuller life and a better world. Some find that the act of extending the highway gives them all they seek from their life-work: these are the pure scientists, and much of our progress derives from them. Others find greater satisfaction in utilizing what has already been built, pausing perhaps to strengthen it here, widen it there: these are the technologists, or applied scientists. A few people combine both functions, driving the road forward into undiscovered territory, then paving it ready for all to use. Whatever our own work may be, we have a joint responsibility to see that the highway is properly and extensively used by all mankind. It is therefore fitting that the British Association is now devoting itself to the additional task of securing the greater use of this highway by all types of people in these islands, more especially as we enter what is often called the Second Industrial Revolution.

---

* Presidential address delivered in Glasgow on August 27 and appearing in the September issue of *The Advancement of Science.*

In the First Industrial Revolution man learnt to convert chemical energy, derived from the reaction between carbon and oxygen, not merely into heat but also into mechanical energy, steam being the key to the process. In the Second Industrial Revolution we are turning from the external properties of carbon atoms to the internal properties of the lightest and heaviest atoms in Nature as a source of energy to expend as prodigally as we like, thus husbanding carbon atoms as a source of materials.

Another feature of the Second Industrial Revolution is the growing interdependence of the sciences as they advance on a broad front. To review the achievements of the past year or two alone, the launching of the Russian and American Earth satellites depended on prior developments in several different sciences and technologies. Chemical rocket fuels, refractory combustion chambers, and radio transmitters which dispatched back to the Earth information of great relevance to the theme of the International Geophysical Year, all played their part. Miniature transmitters themselves followed the invention in the Bell Telephone Laboratories ten years ago of the transistor, which in turn owes its successful development, at least in part, to the perfection of methods for separating traces of boron and other elements from silicon to a degree of purity exceeding one part in a thousand million.

All of us here recognize the creative possibilities of thermonuclear fusion energy opened up by the Harwell and Aldermaston experiments on high-temperature electric discharges. Although most of the neutrons so far produced have not originated from thermonuclear fusion, there can be no doubt that ZETA and SCEPTRE are symbols of man's reach into a future of boundless energy; his grasp of such a prize could well rank as his greatest material achievement in the history of the world. In such experiments as these, as indeed with the discovery of nobelium, a pre-requisite of success is a flourishing electrical industry which can provide many of the tools of nuclear physicists.

Scientific effort on this scale costs money; indeed, the total annual research expenditure in Great Britain alone is estimated to be £300 million. Such effort also costs scientists. Public expenditure on education (including the universities) in Britain is now some £740 million a year; if our universities are to grow large enough to accommodate everyone who could benefit by such an education, instead of merely the 3½ per cent of the population who enjoy it now, then we shall need to contemplate spending something nearer £1,200 million a year. These are large sums, and if, as a nation, we are to stay solvent they can only come from one source, the wealth which we produce.

Business

In this context it is easy to see the importance and responsibility of business, which produces and distributes most of our national wealth. Our capacity to extend our science and education largely depends on our ability to run business successfully. Lewis Mumford in his "Technics and Civilization", written in the 1930's, though he appears to exaggerate their numerical importance, suggests that it may have been no accident that there were merchants of the City of London who played a part in the early days of the Royal Society. He directs attention to the affinity of science and business when he writes: "The power that was science and the power that was money were, in final analysis, the same kind of power: the power of abstraction, measurement, quantification".

On an occasion such as this it is difficult to avoid being at once too general and too particular. I have chosen to speak of business because business is a more comprehensive term than industry. At the same time I intend to limit my scope primarily to the larger units, although naturally I recognize the importance of the smaller organizations—indeed, in manufacturing industry alone, three-quarters of all establishments employ fewer than a hundred people.

Defining the limits of my subject in this somewhat arbitrary way will, for the moment, do service for a formal definition of the term 'business'. After all, it is a vague word, perhaps for euphemistic reasons in the past even deliberately vague. Nevertheless, I venture to put forward three characteristics which I think a business should have if it is to survive and function effectively over a period of years.

(*a*) First, it must contribute to the well-being of the community and its social evolution. I believe it can best do that in three specific ways: by producing goods or services for the community at fair prices; by giving fair treatment in the way of remuneration and working conditions to all who give their services to the business, whether as payroll employees, administrators or scientific staff; and by giving a fair return to those who risk their money in the business, so that, apart from this consideration, they will be encouraged to provide again for further ventures. When business takes on itself the deployment of financial, material and human resources, it also takes on, I believe, the responsibility for seeing that they are properly and effectively used. In other words, it has an obligation to the community; and only in so far as it fulfils that obligation does it contribute to the well-being of the community and justify its own existence.

(*b*) Second, business must have the capacity to change its methods and if necessary even its objectives. It must be constantly alert to see that its products or services meet or anticipate the needs of the public, and to withstand the nipping and eager air of competition whether it comes from advancing techniques or from new entrants into the field.

(c) Finally, if it is to be self-perpetuating through growth or modernization, a business must dispose of its products or services for more than their cost—or in plain language, it must make a profit. That is true of business whether run by private enterprise or by the State ; nor does the political system of the State make any difference to the validity of this notion. Only from the excess of income over expenditure can we finance the expansion of business and science.

This brings me again to the reason why I have chosen to talk about business rather than industry. It is an old saying that money makes money ; by the same token the production of wealth requires the investment of wealth, and such investment can come from a variety of sources. Traditionally, part comes from retained profits, that is from what economists in the past called the abstinence of the individual manufacturer, or in to-day's terms, from the undistributed earnings which companies plough back into the business. Part comes from the banks, though their function in Britain has usually been to provide working capital in the form of loans and overdrafts, rather than to provide fixed capital like the industrial banks of Germany, which played such a prominent part in the organization and growth of industry in that country. Indeed, we can share Disraeli's suprise that the London money market played such a small part in the financing of the railways. In "Endymion", published in 1880, he wrote : "What is remarkable in this vast movement is that the great leaders of the financial world took no part in it . . . even Lombard Street which never was more wanted, was inactive, and it was only by the irresistible pressure of circumstances that a banking firm, which had an extensive country connexion, was ultimately forced to take the leading part that was required". To-day by far the largest volume of capital comes from the investing public as private individuals or financial institutions, working with a vigorous and well-informed Stock Exchange.

There is, of course, no exact relationship between the amount of income which a country ploughs back into capital formation and the rate of economic growth which it achieves. Nevertheless, I think that certain generalizations can be offered. For example, we can compare the experience of the United States with that of Great Britain. Between 1870 and the First World War, the United States devoted more than one-fifth of its national product to home investment, and the United Kingdom only about one-tenth. During that period its national product grew by more than 4 per cent per annum compared with less than 2½ per cent in Britain. More recent history, in spite of occasional and, one hopes, temporary setbacks here, suggests the same lesson : over the past forty years, the United States has invested about half as much again in relation to its resources as we have, and its national product has risen at an average rate of about 3 per cent per annum, against only about 2 per cent in the United Kingdom.

I do not wish to strike a note of disappointment so much as to recall the classic virtues of abstinence, saving and investment. In fact, during the past ten years the amount which the United Kingdom has invested in its productive resources has shown an encouraging growth, with the apparent result that output in manufacturing industry, as a whole, has increased by some 3½ per cent per annum since 1948, compared with about 2½ per cent between the two World Wars. If science has laid the foundation for much of this expansion, business has provided the will and the means to complete the structure, and both must continue to do so.

There is another reason why it is important that this partnership should continue to flourish. We have in the British Isles more than 50 million people who enjoy a material standard of living surpassed in few other countries in the world. Our mineral resources are limited and indeed declining. It is by means of the goods produced by manufacturing industry and the services provided by finance and commerce, in short by business as a whole, that our 50 millions are enabled to live, and on the whole to live tolerably well, in an area too small to feed them, at least by present methods.

All this is commonplace, but like much that is commonplace, it is easily taken for granted until we remember that more than 90 per cent of the world's population live in countries less prosperous than our own, most of them in conditions that we should not dream of tolerating. The world does not owe us a living ; we can only enjoy the standards which our business enterprise and scientific knowledge enable us to earn through our exports. Like all countries depending on their export trade for a livelihood, we in Britain have a vested interest in economically and politically stable conditions throughout the world—and I mean stable, not static, conditions. Stability will not be achieved, for example, if plans for industrialization of the less-developed territories are obstructed from a misconceived notion that we may thereby be able to retain our own markets for that much longer. To those who heard Prof. P. M. S. Blackett's plea last year for technological aid to the under-developed countries, this may sound an unnecessarily narrow approach. But I have deliberately couched my argument in terms of expediency rather than moral compulsion, because it emphasizes one respect in which the combination of science and business seems to me to be vital, and it is this : we must concentrate for our own survival on the development of new products and new processes.

Our old staple exports of textiles, iron and steel, and coal have long since given way to newer lines—vehicles, aircraft, machinery, chemicals and electrical goods. Even here the pattern keeps changing. Motor vehicles, fine and heavy chemicals and so on, are increasingly being manufactured in countries which previously produced only food or primary raw materials. In India, I am told, a company manufacturing diesel engines and electric motors is exporting 30 per cent of its output. Chemicals from Red China and mass-produced toys and torches from Hong Kong are met in many of the world's markets. We are therefore obliged to rely either on selling things which no one else has yet learnt to make, or make as cheaply, or on marketing our skill and 'know-how'.

It is not difficult to find examples of what happens to our business when 'rule of thumbism' is preferred to operations guided and controlled by science and technology. I think there would be general agreement that at various times some of our traditional industries in which we were pioneers have suffered from the lack of proper scientific direction.

In my own industry, organic chemicals once experienced the same neglect. The lead that Perkin had given to our synthetic dyestuffs industry with mauveine was frittered away through lack of scientific effort. In the presidential address to the Chemical Society in 1915 his son, William Henry Perkin Junior, referred to this neglect in these words :

"My experience of the manufacturer in this country is that he is usually merely a commercial person who does not like the expert, and especially the idea of giving the expert a prominent position in the control of his works. Possibly the reason in many cases is ignorance of the value of science, but more probably it is due to the fact that being ignorant of science himself, he feels that if the expert is given too much prominence he must either study himself in order to understand the expert or leave the essential control of the business in his hands. Both these courses are distasteful to the ordinary commercial member of a board of directors; the expert is therefore relegated to the background, and the business comes to grief".

The lesson has not yet been fully learned, for even to-day we meet this attitude. I have a quotation here from a managing director who went on record last May. The scope of his company may be small and may be provincial, but that the sentiment still exists in minds capable of directorial control is significant. He writes: "The place of the expert is not in the saddle but as the assistant and the adviser. The scientist must be on tap, not on top". Such a relationship is very different from the partnership of science and business that I have in mind.

I have considered briefly some reasons why I regard the partnership of science and business as fundamental. To recapitulate, first it is because, if science is to carry forward our social evolution, it needs the financial and productive effort of business; and second, because the prosperity of Great Britain depends on the technologically sophisticated products of our export trade.

A Balanced Partnership: How to Achieve it

(*a*) *The scientist in the business structure.* I should now like to examine how this partnership can be achieved in practice, by considering the place of the scientist in the business structure. In a technological business we can distinguish some six or seven separate functions, depending to some extent on their definition: finance, commerce, personnel, operation or production, design and construction, research and development. I propose not to elaborate on these functions fully, but to touch on one or two of their features.

First, research: research has been called the lifeblood of industry, but I prefer to liken it to the pituitary gland which, I am told, after doing little that is obvious for several years except consume nourishment, at length stimulates other parts of the organism to develop and makes it capable of production.

Research applied to business can take different forms, and one example within my experience may be given. It began with a research manager's conviction that a new inhalant anæsthetic was needed which should have the following properties: it should be a volatile liquid, with high anæsthetic potency, and be free from toxic, explosive and fire hazards. These criteria, he argued, pointed the way to aliphatic halogen compounds containing little hydrogen and especially to compounds with two or three fluorine atoms on the same carbon atom—groupings which are known by organic chemists to be not only unreactive in themselves, but also to strengthen neighbouring carbon-halogen bonds. The resulting inertness is one of the factors in avoiding toxicity; and the use of fluorine rather than other halogens keeps the volatility high. He also proposed a new method of expressing dosages which made it possible to relate, by using a principle of chemical thermodynamics, the amount of anæsthetic in the inspired air to that in the body fluids. This helped in the selection, for biological testing, of compounds likely to have the desired potency, among which the one finally chosen was 2-bromo-2-chloro-1 : 1 : 1-trifluoroethane, a new compound synthesized especially for the purpose.

The major research effort, which for the first two years fell to the organic and physical chemists, had at this stage passed to the pharmacologists, whose screening tests took some three years. They showed that the new compound had not only the properties sought, including a high margin of safety from overdose, but also some unexpected advantages. Clinical trials with successful results began six years after the research started, and meanwhile manufacturing methods were developed by chemists and engineers, leading to general release to the medical profession two years later.

There are several features about this much abbreviated story, some of which are relevant to my present theme. It illustrates, first of all, the systematic application of pure scientific principles to a desired and well-defined end which, though primarily commercial, is not without social implications. Second, the research threw light on the physico-chemical basis of anæsthesia, which time, if no other reason, forbids me to enlarge upon. Third, success was crucially dependent on the existence of a team of specialists in several scientific disciplines and also in the somewhat recondite technology of fluorine; notwithstanding these favourable circumstances and adequate financial backing, the research and development took seven years. Fourth, the distinction between the research and the development function of business is brought out: the original synthetic and early testing work was research, while the development consisted of devising suitable methods of manufacturing and launching the chosen compound, and of studying its clinical effect.

I now turn to the functions of design and construction, which are essentially the field of the technologist or engineer. His grasp of scientific principles, combined with the creative skill of a Telford or a Fowler, fits him above all to build a bridge between science and business. It has been said: "The establishment of the class of engineers . . . is the more important because this class will, without doubt, constitute the direct and necessary instrument of coalition between men of science and industrialists, by which alone the new social order can commence". These words of Auguste Comte remain as fresh and as true to-day as when they were written more than a hundred and thirty years ago.

The production or operation function includes the application of technical methods often according to a routine, though it also demands much planning and organization. Although such work is sometimes considered humdrum and repetitive compared with research and development, it is often essential for it to be done by highly qualified technical men. It is just as great a mistake to believe that unqualified men who come up what used to be called 'the hard way' are generally adequate, let alone best, for production work, as to hold that good technical people are wasted in such jobs as plant management. On the contrary, they must be encouraged to regard it as an interesting and necessary part of their training for higher management.

If there are to be no weaknesses in any one part of the organization, technical staff may have to be moved from one department to another, and this places a vital responsibility on those exercising the personnel function in selection, training and promotion; at the same time it is their duty to ensure that employees can find satisfaction in their work. This function also can be conveniently performed by a scientist, whose knowledge of what the technical departments require helps him to place staff to the best advantage, both of the business and themselves.

On the commercial side also, scientists may be needed in sales, sales service or purchasing, to achieve the best results for a business making technically complex products. I cannot agree that employment of technical men in commercial departments is necessarily wasteful: it gives flexibility within the business, and can often ensure smoother co-operation when a works manager or research chemist feels that his own—the technical—point of view is understood by a man in one of the commercial departments; moreover, as training for higher administrative posts, commercial experience is invaluable to the scientist.

When he reaches such a post, the scientist, recognizing the value of science in business administration, will be well placed to exploit it. I am not thinking here only of new equipment in the office, such as electronic computers or apparatus for sensing letters and figures; science has more to offer than mere tools. It offers the whole philosophy of the scientific approach to the problems of management. I need only mention some of the steps involved: definition of the problem, observation and collation of the relevant facts, formulation of a hypothesis or principle. its testing and its general application.

This approach has been of untold value in the examination of human activity and its measurement, which is usually described as work-study. It has also been very successfully employed in the problems of supply and distribution, in adjustments of stock-levels and in planning of delivery programmes. The full application of such methods usually involves some specialist techniques, especially of a mathematical kind; but even the first qualitative steps of the scientific approach can often lead directly to improvements in business efficiency. All the same, it is worth noting that an otherwise successful application of such techniques can founder on the inability to handle human relationships with proper understanding.

Finance has played a conspicuous part in my address and, in my experience, no technological business ever attempts to progress without continually seeking financial advice. However, I have failed to see in Great Britain an equal acknowledgment that financial institutions need to take the benefit of continuing technological advice, though I am glad that some progress is being made in this direction overseas. For example, I know of a bank specially interested in natural resources which employs full-time geologists. Again, the World Bank Organization in Washington employs technical men not only at headquarters but also to carry out specific missions in various countries. Finance and technology will, I hope, become more and more interdependent as our businesses adapt themselves to current needs.

There is scope then for the scientist to infiltrate throughout almost the whole business structure. That being so, it is pertinent to ask, if scientists are to play an important part in business administration, is the balance between science and business likely to be upset? The answer to this question is, I think threefold.

First, as British industry is at present constituted, the balance is heavily tilted the other way. That is to say, there are still many enterprises which are not employing qualified technical men even in tasks where one would expect to find them, and conversely there are no industries that appear to be harmfully dominated by scientists. This is due partly to the shortage of scientists and technologists with which we are all familiar, but partly also to historical circumstances. In the nineteenth century, due to Britain's wealth of practical engineering experience, theoretical knowledge was under-valued. At the same time, an educational bias towards the classics, based on an aristocratic tradition, sometimes led the second and third generation of a manufacturer's family to forsake the business altogether for politics or the Bar, or if not, at least to be quite unfamiliar with the value of science. Again, as we have seen, in some concerns scientists are relegated to the position of advisers to management and are allowed little part in the active control of the business.

Second, in businesses where scientists rightly play a prominent part in administration, non-technical men who nevertheless have a good understanding of scientific principles are with advantage sometimes put into semi-technical jobs, and this helps to maintain a balanced partnership.

Third, and most important, the balance that we seek must come in great measure from within the individual himself, a balance provided by the education which the scientist and the non-scientist ought to receive. This, besides being central to my theme, is very much the personal concern of many of us here.

(*b*) *Balance in education.* There are three senses in which we might consider balance in education. The first arises from two different conceptions of the purpose of education. On one hand there is the formation of character and the development of intellect and personality. At the other extreme is the concept which I suppose finds its most powerful expression in the educational philosophy of Soviet Russia, that the purpose of education is to provide useful members of society in which the desires of the individual must be subordinated to the needs of society.

I do not believe that these two concepts are wholly conflicting or that the second runs completely counter to the British tradition of individual liberty. A balanced educational system should have room for both. The striking successes achieved by the Russians in science and technology are directly attributable to a system of education deliberately designed to produce large numbers of technically trained men and women with the ability to increase the economic power of the country through industrialization. To this end they established a strong teaching profession to which recruitment is no problem, because it enjoys the highest pay and status of all the professions. Though undoubtedly State direction still has a place in the Russian educational system, its purpose is being achieved to an increasing extent by incentives.

We are proud that the universities of the United Kingdom, despite their growing financial dependence on the State, still retain their academic independence intact. Nevertheless, they have quite properly reacted to the stimulus of the country's needs which have led the older universities, for so long the home of the humanities, themselves to enlarge their science faculties. The new St. Catherine's College at Oxford and Churchill College at Cambridge will give particular prominence to the study of science. The introduction of transfer scholarships to enable promising arts men to turn to science has been readily accepted. More sixth-formers are reading science in the public and grammar schools. Some long-term financial incentives may operate here, but more important has been an intensive propaganda effort which, I hope, will be sustained by the British Association's programme for organizing lectures up and down the country on the lines of those so successfully pioneered by the Royal Institution in London.

So, in framing our formal education, we cannot entirely ignore the requirements of the society on the prosperity of which depend the very conditions in which our educational system can progress; but our society will not be tolerable to live in if its members are not permitted to develop their personalities and talents.

This brings me to the second sense in which I refer to balance in education. I am thinking here of the need for those who study the humanities to have some understanding of the workings of science, and for our scientists to widen their horizons by relating their science to its human context both historically and in terms of the present day. I have in the past on several occasions declared my belief that the gulf which at present separates our scientists and non-scientists is much more easily bridged than is often imagined. For example, the qualities of mind which are fostered by studying chemistry and history are very much alike. Both chemists and historians must cultivate an inquisitive and acquisitive mind. Both need to exercise judgment, leavened with a good measure of scepticism in the exemplary tradition of Robert Boyle. Both must be imaginative, the chemist in advancing hypotheses to predict the future, the historian in doing so to explain the past.

The merits of a balanced curriculum are recognized in Soviet Russia, where children between eleven and seventeen devote something like 46 per cent of their working hours to science subjects, with the emphasis predominantly on mathematics, and another 46 per cent to what we would call arts subjects, with the emphasis here on Russian language and literature. Clearly a correct balance can never be achieved with premature specialization, which the current demands for entry into many universities impose on our most talented students.

There is a third and final sense in which I refer to balance in education. I have said that we demand, from our scientists and non-scientists alike, intellectual qualities, such as curiosity, judgment and imagination. Equally we want our young people, whatever their branch of study, to possess high qualities of character. I need not enlarge on this theme except to say that the society which a balanced partnership of science and business can help to build will as always call for courage, integrity and tenacity. These are some of the ideals that we might have in our minds as we each address ourselves to the problems of education for an age of science.

My theme has been broad and general. It does not call for revolutionary action; it calls rather for sustained progress, and, of the two, that is sometimes the harder to inspire.

In education, Glasgow has an enviable reputation. I have already referred to some of the famous names connected with the University. Alongside its fine academic tradition, we can rejoice in more than 150 years growth of higher technical education. The Royal College of Science and Technology, as its name has been since 1956, can trace its origins back both to Birkbeck's Mechanics' Institution and also to Anderson's College, founded in 1796, where Birkbeck himself taught.

Where such institutions exist to teach and practise science, and where there is still the business acumen and mercantile tradition of the Glasgow 'Tobacco Lords', I hope my plea for extending the partnership between business and science will fall on fruitful ground. In Glasgow, so long ago as 1799, Tennant exploited the discovery of chlorine to found a large chemical business. Again, in this City was discovered the cyanide process for separating gold from its ores, a process which has enabled gold to this day to be mined on a scale massive enough for it to be still a measure of world finance and commerce. Symington's *Charlotte Dundas* and Bell's *Comet* were forerunners in the technology of power-driven ships such as have made the Clyde shipbuilder's skill famous throughout the world. Kelvin's fundamental work on electricity and his maritime interests led him to found a business based soundly on practical physics.

I have tried to show why science and business must be partners: the advancement of science can only be achieved with the resources which business can provide and, if business is to provide them, then it must bring science to its aid. I have also suggested that a truly balanced partnership will manifest itself in the growing use of science and its methods in business; and that it can only come from a balanced education for scientists and businessmen alike.

I believe this balance to be important for our well-being, and as we inaugurate this 120th meeting of the British Association, we can take with sincerity and all humility for our own work, the objective for his college expressed in Anderson's will:

"For the good of Mankind and the Improvement of Science".

SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS

SOME ASPECTS OF THERMONUCLEAR RESEARCH

DR. T. E. ALLIBONE discusses in his presidential address to Section A (Mathematics and Physics) some aspects of thermonuclear research.

If the fusion of deuterium ions is to yield a useful amount of energy, the temperature of the gas must be maintained in excess of 100 million degrees, and it therefore follows that the hot gas must not be in contact with the walls of the vessel containing it. A large current passed through the gas will heat it ohmically and the magnetic force associated with the current will constrict the discharge and draw it away from the walls, thereby compressing it and thus augmenting its temperature. Many investigators have pursued this line of research; British investigators have mainly used toroidal discharge tubes in which a pinched ring discharge is created by electromagnetic induction, whereas American and Russian investigators have used straight discharge tubes, thereby choosing to ignore, for the time being, end losses at the electrodes.

Very large electric currents lasting for short times were readily produced in the straight tubes and bursts of neutrons were detected several years ago. The fact that the bursts of neutrons lasted for only a few tenths of a microsecond and occurred only two or three times throughout a 10-microsecond current pulse was surprising; moreover, the rate of release of neutrons was far higher than could be accounted for. It did not rise appreciably as the discharge currents were increased, and it diminished rapidly if impurities were present. Further study revealed the fact that the discharge developed instabilities in a few microseconds, and at localized constrictions of the discharge, ions were given energies far higher than their mean energy. It was the collisions of these locally accelerated ions which produced the fusion reaction yielding the observed neutrons.

The toroidal discharges studied in the Atomic Energy Research Establishment at Harwell and at the Research Laboratory of Associated Electrical Industries, Ltd., at Aldermaston were maintained for times of the order of a millisecond, during which other forms of instability developed. To a certain degree it was found that these instabilities could be reduced by the application of a steady magnetic field parallel to the discharge path. As the discharge is constricted in the presence of this axial field, currents circulate around the cross-section of the discharge, thus enhancing the field within the discharge and reducing the field outside it. It was found that with optimum values of applied axial magnetic fields the toroidal discharges yielded neutrons over a large fraction of the total duration of the current pulse, both in the apparatus ZETA at Harwell and in SCEPTRE at Aldermaston. Moreover, measurement of the Doppler broadening of some of the spectral lines of impurity elements in the gas indicated ion temperatures corresponding to several million degrees, at which true thermonuclear fusion should yield neutrons comparable in number with the observed neutron flux.

In recent months it has been proved that neutrons and protons released in the fusion reaction in the same direction as the ions in the discharge have energies a little higher than those emitted in the opposite direction; the difference is due to the forward velocity of the deuterium ions at the moment of fusion. This velocity has been found to be appreciably in excess of the mean velocity of deuterium at the temperature estimated spectroscopically. It may be that the spectroscopic measurement is in error, for the discharge, though reasonably stable, can be seen to be moving about rapidly within a confined volume on the axis of the torus, and some of the Doppler broadening may be due to lateral velocity of the beam. To resolve some of the anomalies and uncertainties, ZETA and SCEPTRE are being modified to operate at higher temperatures.

Some of the other ways of attaining high gas temperatures appear to be very promising. Following disclosure of the Russian linear pinch discharge, the Atomic Weapons Research Establishment, Aldermaston, has developed an even faster linear pinch which has produced neutrons; preliminary indications are that these do not arise from instabilities of the discharge. The most recent American and Russian work will be discussed in Geneva on September 4 and may not be commented upon at this moment. Several novel methods of containment of a plasma have been described in recent American literature, but the Russians have disclosed nothing since 1956.

THE CHEMISTRY OF THE TRANSURANIC ELEMENTS

PROF. H. J. EMELÉUS, in his presidential address to Section B (Chemistry), states that it was a natural result of Fermi's observation of the n,γ reaction, whereby an element such as gold could absorb a neutron and by subsequent β-decay be converted into a mercury isotope

$$\left({}^{197}_{79}\mathrm{Au} \xrightarrow{n,\,\gamma} {}^{198}_{79}\mathrm{Au} \xrightarrow{\beta} {}^{198}_{80}\mathrm{Hg}\right)$$

that similar experiments should be done with uranium in the hope of making isotopes of a then unknown element 93. Irradiation of natural uranium actually gave both fission of uranium-235 and neutron-capture by uranium-238. From this confused start, however, clear-cut methods for producing the transuranic elements have now emerged. These are, in brief: (1) bombardment with artificially accelerated particles; (2) neutron bombardment; (3) multiple neutron capture; (4) bombardment with heavy ions. By using these methods, physicists and chemists jointly have now produced ten new elements ranging from neptunium ($Z = 93$) to nobelium ($Z = 102$).

In considering the chemistry of these elements, much attention has been given to the place which they occupy in the Periodic Table, and it now seems certain that they constitute a new group analogous in electronic structure to the rare earth elements. This implies that the 5*f*-electron shell is progressively filled. It would have its maximum complement of fourteen electrons in the hitherto undiscovered element of atomic number 103. This electron assignment is based, first, on the analysis of the emission spectra of some of the elements in question. Secondly, the magnetic properties are analogous to those of the rare earth elements. Thirdly, crystal structure determination of many solid compounds of the new elements have enabled values of ionic radii to be assigned. These show a decrease as the series is ascended, which parallels closely the well-known lanthanide contraction in the rare earth series. Absorption spectra of the transuranic elements also show characteristic sharp absorption bands, associated with transitions within the shielded 5*f*-level.

Chemically, the new elements differ from the rare earths in that, instead of having predominantly a valency of three, higher values are found. This is associated with the great ease with which the electrons are lost.

The maximum valency of 6 is most stable in uranium, but it is also observed in neptunium, plutonium and americium. Curium and berkelium, the next two elements, have valencies of 4, but, so far as is known, the higher members of the series are restricted to a valency of 3. Of the chemical techniques which have been applied in this work two may be mentioned specially. The first is solvent extraction, which is widely used in laboratory work and also plays an important part in the technical separation of plutonium from uranium and fission products. The second technique is ion exchange. The chemistry of the new elements is, for the most part, studied with minute amounts of material far below the limits that could be weighed with a chemical balance. Here the classical techniques of tracer chemistry have been revived and developed. It is the use of tracer technique which has shown that the higher members of the series are restricted to a valency of 3.

The discovery of so many new elements in the past twenty years naturally leads to speculation as to where this process will end. Present indications are that there are very few others which will be stable enough to survive. Stability is limited both by radioactive decay and by spontaneous fission. Nevertheless, a careful search is at present being conducted to extend the field. This work offers an unusual challenge not only because there is such a large unexplored region but also because it calls for very precise and painstaking research.

BENEATH THE EARTH'S CRUST

PLANS recently made to drill a borehole some ten kilometres deep, which may provide information about the Earth's mantle, prompted Prof. L. R. Wager, in his presidential address to Section C (Geology), to review existing ideas on the material of the mantle and to consider the implications if it proves to be similar to the alpine type of peridotites.

Current geophysical evidence suggests a model of the Earth in which the relatively light crust, of variable composition and thickness, rests on the far more uniform and dense mantle at depths of about 10 km. under the oceans and 20–50 km. beneath the continents. The mantle is characterized by a velocity of propagation of compressional waves of about 8 km./sec. and a density of 3·3. It is thought that the sub-crustal material is in a crystalline rather than liquid state down to 2,900 km., beyond which is the apparently very dense liquid core, presumed to have a nickel–iron composition. The facts of isostasy show, however, that, despite the solid condition of the mantle, it must be capable of flowing under sustained stress.

Of the known igneous rocks those with the closest approach to the observed physical properties of the mantle are the peridotites and related olivine-rich types. Some peridotites (for example, those of Sgurr Dubh in Skye) are the result of accumulations of olivine crystals from large masses of associated gabbros and may be described as autochthonous cumulites. Others, however (the alpine type), are common in fold mountains or island arcs, and are not associated with gabbros; these are considered to be possible samples of the upper mantle. It can be shown that basaltic magma could be produced by partial melting of peridotite; a peridotite mantle might therefore explain the world-wide distribution of basaltic rocks.

It is possible to postulate a mechanism for the formation of the Earth's silicate shell based on analogy with layered intrusions. The Earth is considered to have passed through a liquid stage. Convection currents due to cooling from the outer surface would establish a thermal gradient less than the gradient of elevation of melting point due to pressure. Consequently, crystallization of high-temperature minerals might be expected to occur from the bottom upwards. As the column of accumulating minerals increased in thickness, its weight would eventually lead to the expulsion of liquid in the pores, consisting of the components of lower melting point, from the lower parts.

The nature of the crystal phases earliest to separate is uncertain. But by the time the accumulation had reached about 200 km. from the surface the liquid was probably close to forsteritic olivine in composition, and olivine, enstatite and chrome spinel would be the primary minerals precipitated. Later, plagioclase and augite would be expected to form, and finally, when crystal accumulation had reached to within about 10 km. of the surface, a residual liquid of granodioritic composition would be expected, which further cooling would form into the crust. During this long process, convective action must have been modified partly by the heating effects of the radioactive constituents of the fluid expelled from the mush and partly by the changing mechanical properties of the solidifying mantle. In particular, convection currents would be very restricted in the later stages, when the crust had solidified. Perhaps a major convective overturn in the mantle at an intermediate stage, before final solidification of the crust, was responsible for pushing the sialic scum into the restricted areas now occupied by the continents.

SOME BIOLOGICAL EFFECTS OF LOW TEMPERATURES

THE presidential address by Dr. A. S. Parkes to Section D (Zoology) discusses the biological effects of cold. This subject has attracted many of those prominent in the history of science, including Robert Boyle, Réaumur and Spallanzani. These early workers relied on natural conditions or simple freezing mixtures to obtain their effects, but they contrived to experiment with a wide variety of living cells and organisms. During the past century, the availability of solidified carbon dioxide and the liquid gases has enormously increased the range of temperatures over which experiments can be conducted, and naturally the range of experimental material has also been increased. At the outset we can distinguish two main branches of the subject: first, the study of the effect of cold on the whole organism, whether it be an insect or a man; and secondly, the study of the effect of cold on the isolated cells or tissues, or even whole organs of an organism. From our present point of view, what is important is the internal temperature of the cell, tissue or organism, the environmental temperature being of importance only in so far as it influences the internal temperature.

Cold-blooded animals allow their body temperature, within certain limits, to fluctuate in keeping with environmental temperature. Some of the lower cold-blooded animals, notably insects, have a remarkable tolerance for cold, not merely in the range of temperatures above zero but actually in a range well below zero. This tolerance appears to depend partly on a striking capacity for becoming supercooled and, in some instances, on the ability to withstand the crystallization of the body-water as ice. This tolerance of sub-zero body-temperature under natural conditions is not seen in the higher poikilotherms, and stories of fish and frogs frozen solid in blocks of ice are almost certainly apocryphal.

In contrast to cold-blooded animals, warm-blooded animals maintain a closely controlled body-temperature which is almost always between 37° C. and 41° C., and which in most parts of the world is much above environmental temperature. Some warm-blooded animals, however, hibernate during the winter, and in this state they take on many of the characteristics of cold-blooded animals. Non-hibernating warm-blooded animals were commonly supposed to die if body temperature was artificially reduced to a level at which heart-beat and respiration ceased. It is now known, however, that under laboratory conditions a warm-blooded animal such as a rat or a hamster can be resuscitated from deep body temperatures below zero. As the body-temperature goes below zero the animal either supercools or begins to freeze. The former process is comparatively benign; the latter has so far proved lethal when pushed to a stage at which more than 50 per cent of the body-water is converted to ice.

It is more easy to generalize about isolated cells and tissues. Among the invertebrates, certain cells survive being subjected to extreme cold, but almost all the normal cells and tissues of vertebrates are killed by freezing and thawing under ordinary conditions, and little progress was made in this field until it was discovered that certain substances, notably glycerol, protect cells and tissues against the otherwise fatal effects of freezing and thawing. By the use of glycerol it has been possible to freeze certain types of mammalian cells and tissues, especially spermatozoa, red blood cells, and endocrine tissues, and keep them at low or very low temperatures for long periods, and afterwards to thaw them out and use them effectively for insemination, transfusion or transplantation. It may be that further refinements of technique will make it possible to dry these cells from the frozen state and permit long-term storage at ordinary temperatures.

The study of the biological potentialities of low temperatures is at present one of the growing points of biology, and it is likely to contribute substantially to man's powers over Nature.

THE ATLANTIC ENDS OF EUROPE

THE presidential address by Prof. E. E. Evans to Section E (Geography) presents some results of researches into the origins of human settlement and the development of land use and social systems in the Atlantic fringe of Europe, with special reference to Highland Britain and Ireland. The environment of the Atlantic Ends is characterized by deeply indented coasts backed by infertile massifs of ancient rocks relieved by scattered patches of recent glacial or fluvial deposits. Climatically, the mild winters, heavy all-season precipitation and high values of wind and cloud have favoured pastoralism rather than arable farming. Consciousness of an Atlantic culture-area extending from Galicia to Norway was strongest in the early days of Christianity, by which time fishing and seafaring, extensive stock-rearing and restricted arable farming were well adapted to the three major elements of the environment. Independence, pride of blood and strong personal loyalties were characteristic features of society. The prevailing form of settlement was the joint farm or extended-family holding, a cluster of peasant homesteads possessing common rights in infield, outfield and mountain grazing. These house-clusters must be distinguished from the villages of the European plain, and it is suggested that they are a type of prehistoric settlement which persisted in the far west. Further, the Atlantic long houses, only one room wide, are similar in plan to those of neolithic Europe. It is argued that the system of co-operating kin-groups was maintained along the Atlantic in environments which called for common effort yet could be utilized without the technological equipment and complex organization of a manorial system. Early Indo-European institutions, reaching the west probably during the late Bronze Age, were absorbed and became fossilized.

Already in the third millennium B.C., shifting cultivators of the western Neolithic had reached the Atlantic Ends and tapped the fertility of forest soils with crops of wheat and barley. During the early Metal Age, when supplies of tin, copper and gold became commercial assets, the fringe experienced a golden age. In the sub-Boreal, dramatic environmental deterioration affected upland areas, where bogs replaced forest, following clearance by man and podsolization. The megalithic cult had been widely adopted and the great stone monuments, the abodes of powerful ancestral spirits, became symbols of a lost fertility.

After the introduction of oats and other innovations in the Early Iron Age, a readjustment allowed a second blossoming-period in the sixth to ninth centuries, and a third phase of expanding food resources and population followed the coming of the potato. With the enclosure movement and the scattering of farms, commercial agriculture came to be based on the old outfield practice of 'taking the plough round the farm' by using long leys.

Within the British Isles, the Atlantic inheritance had made a distinctive contribution to British life, and to overseas lands through heavy emigration, and Prof. Evans makes a plea for the preservation of regional variety in a world weighted in favour of uniformity. There is a danger that movements towards the restoration of self-government will lead to isolation. Along the Atlantic shores, peasant attitudes of immemorial antiquity have not entirely succumbed to the impact of a money economy. Idealization of the past and a reverence for spiritual values, coupled with suspicion of impersonal external authority, have sprung from the experience of living in the Atlantic Ends.

BRITISH ECONOMY UNDER INFLATION

PROF. A. J. BROWN, in his presidential address to Section F (Economics), states that the outstanding feature of the British economy since the War has been the low level of unemployment in comparison with both pre-war experience and the most sanguine war-time expectations. This low level appears to be explained in part by an alteration in the behaviour of employers. It is noteworthy that variations since the War have been mostly in hours of work or, secondarily, in the number of people available for employment, whereas before the War they took place mainly in the proportion of the labour force unemployed.

The great cause of high and steady employment since the War has, of course, been freedom from fluctuations in demand. Most of all, we have been remarkably free from any major fluctuations in world demand for our goods and services. There has, however, been a very marked fluctuation in internal demand for inventories, which may be a new phenomenon in Britain, though it is well known in the United States, and which might have been expected to produce marked fluctuations in employment such as have occurred in America.

The main reason why Britain has escaped these fluctuations in employment is that variation in demand for inventories has been largely taken up by variation in imports, but the method of financing government expenditure has helped somewhat and there has been fortuitous assistance from variations in defence expenditure and also from variations in the prices of our imports.

The question arises whether the high level of employment has diminished the adaptability of the economy. A simple measurement of the amount of change in the British economic structure in the years 1948–56 shows it, in fact, to have been almost identical with that experienced in the years 1929–37 (the amount of change in the intervening period 1937–48 having been about twice as great). It is natural to inquire further whether this adaptation to economic forces since the War has taken place by a different market mechanism from that of the 1930's. It proves to be the case that, on the whole, the industries which expanded relatively to the rest in the 1930's were not those in which earnings rose most. On the other hand, there is a definite tendency for the industries which have expanded most since 1948 to have obtained their increased share of the labour force by raising their earnings in relation to others.

The record of progress in Britain in regard to the standard of living since the War has been good by previous standards but not striking in comparison with other countries. It is very difficult to find any close connexion between this progress and the timing of new investment; in fact, in manufacturing industries especially, the striking feature of the past ten years has been the increase of output in relation to both labour and capital.

The amount of saving (and hence of investment) in the economy does not seem to have been adversely affected to any marked degree by post-war inflation. Such reduction as there has been in it after allowance is made for the level of disposable real income does not seem too great to be accounted for largely by change in distribution of income. A further indication that our inflationary experience is not likely seriously to have affected saving is that there is little sign in the prices of assets or in the level of interest-rate in relation to money holdings that steady expectations of rise in prices have had much influence. It may be concluded that Britain's record of high employment and economic progress since the War has been reasonably satisfactory in many ways, but that a considerable part of our success is due to external circumstances which may change and with which we may not have adequately equipped ourselves to deal.

HEAT AND THE ENGINEER

PROF. O. A. SAUNDERS, in his presidential address to Section G (Engineering), comments that in pursuing his art the engineer must always encounter many problems of heat and heat transfer. These occur in the generation of power from heat, in the control of heat-influenced processes, and in many problems of engineering design where the production of heat is a nuisance. In the field of power generation, interest is increasing in the direct conversion of heat into electricity by some form of thermionic converter which would allow the elimination of expensive turbo-alternator machinery, and would have many applications for small generating sets even though the thermal efficiency were not high. The possibility of direct conversion of nuclear energy into electricity, although remote at present, would have far-reaching effects on power stations of the future.

The engineer is vitally interested in progress of the fundamental science of heat transfer, which has advanced greatly during recent years. By the use of numerical methods and computing machines, it is now possible to solve many problems theoretically, and the field of laminar flow convection is now well covered. For turbulent flows, however, where the greatest practical interest lies, empirical methods are still needed, although the understanding of these flows has improved. The gas-cooled nuclear power reactor has posed some interesting problems of turbulent-flow heat-transfer, and their solution is of great practical importance.

The regenerator is an attractive principle of heat exchange, and new ideas for rotary regenerators have come forward in recent years; but it is difficult to design a satisfactory mechanical arrangement, especially for the moving seal between the two fluids. The prospects of the gas turbine for automobiles and other mobile applications would be transformed if a reliable and efficient regenerator could be developed.

The problems of aerodynamic heating have been increasingly felt in high-speed aircraft and missile design, and novel means of overcoming them have been put forward, including sublimation of the surface layer of the material in the case of missiles and the use of cold fuels such as liquid hydrogen for supersonic aircraft. There are many other interesting new lines of research and development in industrial heat transfer. The dropwise condensation of vapours, which would give a useful reduction in size of power station steam condensers, has been successfully promoted chemically for copper-alloy tubes, but for stainless steel surfaces such as are used in condensing organic vapours it has not so far been possible to find a promoter which will adhere satisfactorily. The control of radiation from luminous furnace flames has been improved by research on large-scale furnaces, and, for example, the use of pitch creosote to control and improve the relation from non-luminous coke over gas flame has been successfully worked out.

In electrical engineering, the use of hydrogen, especially at elevated pressure, for cooling turbo-alternators, has been the biggest factor in improving the performance of machines and has made possible the increase of the output of the single unit from 200 to 350 megawatts. Liquid metals as heat carriers have received special attention from the nuclear reactor designers because of the favourable neutron-capture properties of sodium and potassium and their alloys and because of their high rates of heat transfer. It is likely that these metals will find new uses outside the nuclear field now that handling problems are being overcome.

Creative research, inventive development, inspired design and novel construction in the field of heat transfer are all needed to keep pace with the needs of modern technology.

THE STUDY OF FOLK LIFE AND ITS PART IN THE DEFENCE OF CIVILIZATION

IN his presidential address to Section H (Anthropology and Archæology), Dr. Iorwerth C. Peate points out that anthropology—the science of man—is a vast field of which folk life, like archæology, is a small corner. The change of the title of Section H in 1947 from "Anthropology" to "Anthropology and Archæology" is to be deprecated, since anthropology is a large enough umbrella for us all. The student of folk life is concerned with the study of every stratum in the community, and with all communities except those completely affected by a high degree of industrialization.

Folk life as a field of research has developed from the study of collections of 'bygones' in museums, and it is therefore often believed, erroneously, that it is concerned only with the post-medieval period. There is no date-line at which the study begins. Nor can it be said to end with the Industrial Revolution, for even in communities affected in part by industrialization, much evidence remains of the persistence of traditional ways of life. The traditional cultural pattern, from its early beginnings to the present day, is the basis of study.

Pioneer work in the Scandinavian countries, particularly the work of Dr. Sigurd Erixon, the late Åke Campbell and the late Wilhelm von Sydow, established the standard by which most work on the subject must be judged. Certain aspects of the study may be mentioned. (*a*) The study of houses. Most major works on English architecture are of little use in the study of folk life, for they ignore the smaller buildings such as farmhouse and cottage. Regional studies such as Fox and Raglan's "Monmouthshire Houses" are urgently needed before any interpretative work can be carried out. (*b*) Similar records are required for problems such as transhumance. (*c*) The student of folk life should be chary of accepting uncritically such theories as those of a time-lag in fashion in areas far removed from a metropolis or of national forms of costume—theories which are based on insufficient evidence and basically unsound.

The study of folk life cannot be confined merely to visual materials. Speech and local dialects are an important part of it: vocabularies of the hearth and home, those relating to domestic animals, agriculture, festivals, religion and all social activities. The work on oral traditions carried out in England, Scotland and Wales should, Dr. Peate believes, be financed by the State. The refusal by the State to give an emergency grant to record the traditions of North and South Uist is thoroughly to be deplored.

We study the eternal task of 'building up a civilization in Nature' in all the little nations of Europe. Their traditions are the buffer between the passive barbarism of the West and the active barbarism of Eastern Europe, between two world forces which threaten to reduce the world to the level of brute sensation. The study of folk life has, therefore, a purpose beyond the mere limits of an academic discipline: not only does it contribute to the sum of scientific knowledge but also it assists in the rehabilitation of a degraded civilization.

SOME ASPECTS OF CELLULAR DIFFERENTIATION

DR. E. N. WILLMER, president of Section I (Physiology), comments that the manner in which the cells of a highly developed organism such as man differentiate is not a problem which can ever be solved by the study of that organism alone. For example, in human embryology there comes a time when certain connective tissue cells, the fibroblasts, begin to produce collagen and form an inter-cellular fibrous matrix. The problem of the formation of these fibres was not, however, first solved for man; its solution must have already been achieved many millions of years ago when the calcareous sponges were first evolved, for they, like the majority of animals in all groups, form a ground-substance with collagen fibres.

It may therefore be more profitable to investigate the collagen-forming cells when they first appear, as, for example, in sponge embryos, than to study them only in what may be a specialized form in man. In the embryos of calcareous sponges, the fibre-forming cells originate from the flagellated cells which constitute the animal pole of the embryo. The posterior amœboid cells do not apparently contribute. An investigation of the difference between these two types of cell may therefore yield information about the original conditions which led to the production of fibres. At an even more primitive level, study of an amœba (*Naegleria*), which shows dimorphism, in that it may exist in either an amœboid or a flagellate form according to the ionic concentration of its surroundings, emphasizes the influence of the ionic environment on cell form. It perhaps also suggests the possibility that the anterior and flagellate cells of the sponge may react in one way to their ionic environment while the posterior amœboid cells react in an opposite manner, and that the two types of cells are combined in one embryo in such a way as to maintain the ionic stability of the organism as a whole.

The further possibility that, since the fibre-forming cells of the sponge are formed from the flagellate cells of the embryo, the mucoproteins and fibres (or their precursors) are in some way related to the maintenance of ionic equilibrium by the cells seems to be one worth considering. The suggestion is therefore made that the preservation of ionic equilibrium by a cell may involve the production of certain metabolic by-products; for example, hexosamines or related substances from which mucoproteins and mucopolysaccharides can be built on one hand, and glutamic acid, proline, or hydroxyproline from which collagen fibres can be synthesized on the other. A cell which is moving cations across its membrane in one direction may perhaps drive these by-products in the other direction. Some cells derived from the flagellate cells (for example, fibroblasts) would thus be in a strong position for forming intercellular matrices, because they normally liberate the necessary precursors, whereas other cells, for example, those corresponding to the amœboid cells, would be more likely to store the mucoproteins within their cytoplasm and have to turn the glutamic acid, proline, etc., to other uses within the cell.

This is certainly an over-simplification of the position, but it may serve to illustrate a general principle. It may therefore be more profitable to tackle cellular differentiation from rather more basic premises, and to study the origin of the simplest colonial forms, for it was they who were the first to solve the problems of cell adhesion, of ionic and osmotic balance, and of mechanical stability. If it could be discovered how they achieved these ends, and how their cells became differentiated accordingly, then the mutual relationships of cells, in higher organisms, and the influence of hormones and 'organizers' upon them, might be made somewhat more easily intelligible.

SOME PROBLEMS OF COLOUR VISION AND COLOUR BLINDNESS

THE presidential address to Section J (Psychology), by Prof. R. W. Pickford, marks the jubilee of psychological studies in Glasgow, for the lectureship in general and experimental psychology in the University of Glasgow was established by the University Court in 1907, and H. J. Watt, the first lecturer, began his duties in 1908. The Laboratory of Experimental Psychology was established in part with a donation in 1908, and a gift of auditory apparatus from his collection, by friends of Prof. John G. McKendrick, formerly professor of physiology in the University of Glasgow.

The history of colour blindness tests has shown a number of interesting developments, from the use of coloured wools by Holmgren, to Edridge-Green's lantern, beads and spectrometer, and other and better lantern tests have been devised, notably by Giles. The most popular tests of colour blindness have been pseudo-isochromatic charts and tables, such as the Stilling, Ishihara and other tests. Farnsworth's and Dimmick's tests are great improvements upon them.

The Rayleigh equation of a mixture of lithium red and thallium green, matched against a standard of sodium yellow, has led to the Nagel anomaloscope, which uses spectral lights, and to several other kinds of anomaloscope, which are mostly filter instruments. Similar equations, especially of blue and yellow, or of blue and green, have been utilized as tests for blue and yellow vision.

The results of anomaloscope tests show an instructive grouping of colour-vision defects and variations, depending on combinations of variability of matching range, deviation of mid-matching point and shortening of the red or violet end of the spectrum. There are two main types of red–green blindness: (1) protan defects, including protanomaly, extreme protanomaly and dichromatic protanopia; (2) deutan defects, including deuteranomaly, extreme deuteranomaly and dichromatic deuteranopia. In addition, there are tritanopic defects, or yellow–blue blindness, and minor forms of variation along the lines of the protan, deutan and tritan defects. Total colour blindness should also be mentioned.

Red–green blindness is a sex-linked Mendelian recessive character, found in about 7·5 per cent of men in Britain. It shows interesting variations of frequency in different geographical areas and racial groups, the lowest percentage reported among men being 0·5 per cent in Fiji by Geddes, and the highest probably being 12·8 per cent among Toda men by Rivers. Co-ordination of testing standards is not easy. Yellow–blue minor defects are more frequent among dark-skinned peoples, but red–green defects are less frequent among them than among whites.

It is generally agreed now that there must be two series of major red–green defective genes, with separate loci on the X-chromosome, and about three alternative forms in each series, in accordance with the classification given above. A woman may inherit two types of defective gene, one from each parent and from different series, and yet have apparently normal colour vision. In certain cases of sex reversal, as in Klinefelter's and Turner's syndromes, in which the individual has developed sex organs contrary to the 'genetic sex', the frequency and pattern of inheritance of colour blindness is that expected for the 'genetic sex' rather than for the masculine or feminine phenotypes. For example, in an interesting pedigree there is a male 'woman' of the type found in Turner's syndrome, who must have inherited her colour blindness from her mother, for her father has normal colour vision. Colour blindness is an incomplete recessive, since women heterozygous for it show minor defects more frequently than normal homozygous women.

Colour blindness requires three general hypotheses to explain its nature and variations: (1) the 'loss' hypothesis, which assumes the absence of certain functions or sensory end-organs; (2) the 'collapse' hypothesis, which assumes the failure of certain functions to differentiate groups of light waves normally distinguished; and (3) the 'swing' hypothesis, which assumes variations in the distribution of sensitivities which may otherwise be normal. It seems that protanopia is a loss defect, deuteranopia is a collapse defect and that the various types of anomalous colour vision are due to swing defects either alone or in combination with one, or both, of the others. The whole subject is extremely complex.

The most favoured theory of colour vision is still the trichromatic theory due to Young and Helmholtz, but there have been many advocates of others, notably polychromatic theories and the four-colour theory due to Hering. At present, it seems that the trichromatic theory would be adequate to account for all forms and variations of colour vision and its defects, provided that we are allowed to introduce the concept of swing defects.

The studies of colour vision defects and of tests for their detection and measurement are of the greatest importance, especially where life and safety depend on the use of colour signals, and also in those industries in which fine colour discrimination and judgment are required.

THE CAPE AS AN ANCIENT AFRICAN FLORA

THE presidential address to Section K (Botany) by Prof. R. S. Adamson points out that the so-called Cape flora is a very distinctive one in Africa which has its main development in a small area in the extreme south-west of the continent. The flora is a very rich one with a high proportion of endemics, and is made up of portions with different geographical relationships.

Though this flora in its typical form is confined to the south-west corner, there are distinct traces of it in other regions, notably on the higher mountains throughout the continent, and also to a lesser extent in the Mediterranean flora of the north coast of Africa. The floras of the adjacent islands, Madagascar and the Atlantic Islands also show clear affinities. All appear as old floras and floras with a common origin.

Though the Cape region is the largest and much the richest of the portions existing, it is not suggested that it was the source from which the others arose. Instead, the portions are regarded as being remnants of the area of a once widespread flora that covered the more temperate parts of the continent. Changes of climate and of geography have resulted in the disappearance of the flora in the intervening areas. The original flora must have existed at a time when islands such as Madagascar were united to the mainland.

The existing parts have undergone development and change since their establishment, especially in the Cape region, where the area is largest and conditions have remained favourable.

In attempting to trace the possible origin of this old flora, its close relationships with those existing in south and south-west Australia and in the south-west of South America are noted. The most probable explanation is found in the theory of continental drift. The old flora was one that became established when there were land connexions. Those existing to-day are the descendants of the separated parts, each of which has become modified by local developments and by immigration from adjacent regions.

THE PARTNERSHIP BETWEEN INDUSTRY AND EDUCATION

SIR WILLIS JACKSON says in his presidential address to Section L (Education) that he would like to interpret his selection as president of the Section as a recognition of the importance which is attached to the place of industry in the educational structure of Britain. It affords him the opportunity of paying tribute to the considerable educational service which is being performed by many industrial concerns, and to the part they have played towards establishing within the schools a belief that industry can offer to those with a sense of vocation as satisfying a career as the 'learned' professions which have traditionally attracted a dominant proportion of our most able young people. The increasing number now devoting themselves to a prolonged study of science and technology means more than a mere recognition of the material importance of scientific and technological achievement, and more than a growing acceptance that scientific subjects, properly taught, are no more specialized than, and provide as good a vehicle of education as, arts subjects. It means that industry is coming to be seen not merely in terms of machines and technical processes but also of men of character and stature; and that it provides great opportunities not only for the exercise of scientific and technological skill but also for co-operation in service and in human relations.

Sir Willis Jackson also makes forthright comment on the fact that the contribution of very many other firms towards the further education and the practical training of their juvenile recruits is much less than is demanded both by their own best interests and by the well-being of the country as a whole. He refers to the increase since the War in the willingness of industry to release its young employees to attend day-time technical courses, but also to the wide discrepancies which exist between different branches of industry and to the enormous scope for further improvement. His main anxiety, however, concerns the dearth of satisfactory facilities for apprentice training at all levels, which, unless corrected as a matter of urgency, is likely to frustrate the developments now taking place within the schools, technical colleges and universities of Britain, and to produce a serious national situation when much increased numbers of young people become available for employment in the early 1960's. After outlining the comprehensive training schemes organized by some large industrial concerns, he advocates a considerable expansion of co-operative arrangements among groups of small and medium-sized firms. In his opinion, however, these will develop too slowly if left to the initiative of industry alone, and that in any event the time has come when the national interest requires independent assessment of the adequacy and effectiveness of present-day concepts of apprentice training. So far as graduate and student apprentices are concerned, there are at least signs of machinery, within some of the professional institutions and within the National Council for Technological Awards, by which advice may be given and appropriate pressures may be applied. But even these do not exist in respect of the nationally no less important spheres of technician and craft training. He compares the caution of the recent Carr Committee report on "Training for Skill" with the forthright recommendation in the 1944 report of a conference of representatives nominated by the Manchester and

District Committees of the Engineering and Allied Employers National Federation, the Amalgamated Engineering Union, the major engineering institutions and the Regional Advisory Council for Technical and other Forms of Further Education, that a National Apprentice Council and associated regional councils should be established, and that their directing activities should be supported by a national fund provided jointly by the State, the local education authorities, and the employers and trade unions concerned.

After referring to the serious shortage of science and technical teachers, Sir Willis says that the more effectively industry fulfils its responsibilities in the fields of education and training the fuller will be the benefit which will accrue to it—employer and employee alike—and through it to the nation.

DIGESTION IN THE RUMINANT

IN his presidential address to Section M (Agriculture) Dr. D. P. Cuthbertson points out that the outstanding difference between the ruminant and other herbivores is that the former pre-ferment their food through microbial action in the first two compartments of the complex stomach—the reticulo-rumen sac—before digestion by enzymes secreted by the digestive glands begins in the abomasum or fourth stomach. Considerable absorption of the soluble products of microbial activity takes place from this sac. In the third compartment, the omasum, absorption of water is the main feature.

The reticulo-rumen sac thus forms a fermentation vat in which bacteria and protozoa are established under highly reducing conditions when the animal is quite young. Fermentation of cellulose through microbial activity takes place there; otherwise it would be unavailable through lack of a cellulase in the digestive glands. In grass itself, and especially in root crops, other fermentable carbohydrates exceed cellulose in amount and being more soluble and less resistant structurally and mechanically than cellulose, are more readily fermentable by a much wider variety of micro-organisms, but not necessarily to the same ratio of desired products.

The reticulo-rumen sac is never empty, and constitutes a functional field in which all the activities are organized for utilization of microbial products and all factors therein make for a steady state. The activity of the salivary glands, the process of rumination involving re-mastication, the absorption of the products of microbial activity and the interchange of ions between rumen contents and blood—in the case of sodium against the concentration gradient—all contribute to the continuity of microbial action during the whole life of the animal, and produce conditions which one can scarcely hope to reproduce *in vitro*. Nevertheless, by observation of the micro-organisms—the bacteria and the protozoa—at the site of their attack on food particles, and in isolation in culture, and by a study of the soluble products of fermentation and their absorption, much information about this microcosm has been obtained.

Consideration is also given by Dr. Cuthbertson to the early development of the ruminant: to the role of the saliva, and to the passage of food through the alimentary tract.

In the rumen, dietary protein is subjected to fairly vigorous hydrolytic conditions, and the low-molecular products, including amino-acids, are then assimilated by micro-organisms and incorporated into their body protein or, if amino-acids accumulate in excessive amounts, the micro-organisms acquire the power to ferment them deaminatively to ammonia, short-chain fatty acids and carbon dioxide. Further, it is known that urea and ammonia can also be utilized by the micro-organisms for elaboration of their own body proteins. These proteins are of good biological value and are presumed to be digested in the abomasum and small intestine in similar fashion to that taking place in the non-ruminant.

When cellulose and starch are broken down by the micro-organisms to soluble sugars, these, like other soluble sugars in the diet, are fermented to give short-chain fatty acids. These acids, together with those derived from protein, are absorbed from the rumen into the blood stream. It has been calculated that for hay-fed sheep, about 70 per cent of the total energy requirements is provided by these fatty acids. These short-chain acids are quantitatively much more important than glucose as a source of energy.

While the microbiological synthesis of fat-soluble vitamins (other than vitamin K) has not yet been unequivocally demonstrated, the metabolic needs for the various B vitamins are met by synthesis in the reticulo-rumen through microbial activity. The synthesis of vitamin B_{12} is conditioned by the cobalt content of the feed. Ascorbic acid appears to be synthesized in the ruminant's own tissues.

This pre-gastric microbial digestion confers important benefits upon the ruminant. Energy from fibrous foods, which could not otherwise be obtained, is more efficiently garnered and the available energy is yielded over a longer period of time, so that the animal is more resistant to periods of starvation; the uptake of nitrogen is controlled and that from non-protein sources utilized more efficiently via microbial proteins; and considerable synthesis of vitamins takes place. This aspect of the physiology is as fascinating to the investigator as it is important for the husbandman. Further advances should help to clear our understanding of some of the so-called 'metabolic' diseases.

THE CULTURAL VALUE OF LOCAL SOCIETIES

LORD BOYD-ORR, in his presidential address to Section X (Assembly of Corresponding Societies), remarks that though all governments are clamouring for more science, human society is suffering acute indigestion from an overdose of science. For example, it is estimated that in a third world war with the weapons we already have, 90 per cent of the people in the northern hemisphere would be wiped out. One would have thought that that was plenty to be going on with, yet in government 'hush-hush' laboratories there is probably more research to improve weapons of war than in any other field.

In industry, science has increased the output per man and the total capacity for production to such an extent that although a large part of industrial potential is engaged in producing armaments, factories produce goods for peaceful uses faster than they can be dispersed and consumed, so that production has to be slowed down with resulting unemployment which, in the United States where technology is most advanced, at present exceeds five million. To find work for people is now a major domestic political problem. But science still advances. It is estimated that when automation and other improvements foreshadowed are applied, one man will be able to produce as much as four or five at present.

Equally great is the advance in biological science. Where modern medicine has been applied, the expectation of life at birth has increased by twenty years since 1900. It is now being applied in all countries and in forty years the present population of the world is likely to be doubled, and doubled again in the succeeding thirty years. Yet medical research is being intensified—and rightly so. But too little thought is being given to how long the Earth will be able to support its human inhabitants.

Thus, in one generation, the advance of science has made war obsolete unless, of course, our civilization lacks the intelligence to avoid committing suicide. It has lifted the burden of labour from man's shoulders and changed scarcity, with inevitable poverty, for the majority of the people in the world to one of potential abundance for all mankind. It has made it possible to free the human family from most of the suffering and premature death which has afflicted it since man first appeared on the Earth.

What is needed to-day is, not more science, but changes in the structure of society to enable people to enjoy the rich fruits science has already made available. Governments—even to some extent, totalitarian governments—cannot bring about big changes until people realize the need for them. The British Association, especially by its presidential addresses, is doing much to enlighten the public on the powers of science and the problems they have created. It is suggested that this should now be its main function.

Several sections might consider common big issues and report their findings in non-technical language. Section X, which consists of about 170 allied societies the members of which represent the more intelligent part of the population of Britain, might consider the changes needed to adjust society to the new atomic age. By doing this it would promote knowledge, wisdom and benevolence, or in other words 'culture', which this scientific age so sadly lacks.

The British Association can perform an even more valuable ervice than it has done in the past by adapting its meetings to throw the searchlight of science on world affairs.

THE GLASGOW REGION

The Glasgow Region

A General Survey. Edited by Prof. Ronald Miller and Dr. Joy Tivy. Pp. xix + 325 + 20 plates. (Glasgow: Local Committee of the British Association for the Advancement of Science, 1958.)

WHILE it can scarcely be said that the various centres visited by the British Association vie with one another in the production of a handbook to the neighbourhood, the local committees have certainly succeeded in producing a valuable series of books, impressive both in quality and in size. The handbook for the Glasgow meeting is no exception. It is a very substantial volume, well supplied with plates and other illustrations, and embellished with the University and City arms on the covers.

The volume has been prepared under the editorship of Prof. Ronald Miller and Dr. Joy Tivy, of the Department of Geography in the University of Glasgow, who emphasize in the foreword that it has to serve a double purpose: it must introduce the region to the visitor and it must give the local reader food for thought, thus providing for both divisions of the British Association membership. This they have succeeded in doing, mainly by means of a series of chapters surveying different aspects of the scene.

Prof. Miller opens with a chapter on the geography of the region. This is followed, quite naturally, by a résumé of the geology by Prof. T. Neville George. C. A. Halstead deals with the climatology. The chapter on land utilization is divided into three parts, written by Prof. John Walton (vegetation), Prof. Donald S. Hendrie (agriculture) and J. E. James (forestry) respectively. Biology of the Clyde and its associated waters is dealt with by Dr. W. D. Russell Hunter, who also provides some notes on the land animals of the area. The Clyde in prehistory and in the Roman period is discussed by Dr. Horace Fairhurst and Dr. Anne S. Robertson respectively. Chapters on Glasgow itself and its history to 1750 (Prof. George S. Pryde) and the industrial and commercial developments (John B. S. Gilfillan and H. A. Moisley) bring the story to 1914. There follow chapters on the engineering industries (Drs. James Orr and Sarah C. Orr), fuel and power (Dr. R. Common on coal and gas, and D. R. Diamond on electricity and petroleum) and the economy of Glasgow (Prof. Alec Cairncross). Human problems are the subject of chapters on population distribution (Dr. Joy Tivy), the Glasgow overspill problem (Berenice D. Baker), transport (John F. Sleeman) and Glasgow's spheres of influence as a regional capital (H. A. Moisley). The histories of the University of Glasgow and of the Royal College of Science and Technology are briefly summarized by Prof. John D. Mackie and Charles G. Wood respectively, A. McLaren Young surveys the fine arts and Catherine B. Smith provides brief notes on research institutions in the area.

"The Glasgow Region" is a worthy addition to the series of handbooks prepared by the enthusiastic and hard-worked local committees in the cities visited by the British Association. For the teacher of geography they are veritable mines of information, up to date and authoritative, for regional studies; for the visiting member of the British Association they are equally useful for reference purposes, and also as reminders of many interesting and valuable occasions. There is no index.

THE ROYAL COLLEGE OF SCIENCE AND TECHNOLOGY, GLASGOW

NEW ENGINEERING BLOCK

IN the years between the two world wars, the engineering department of the Royal Technical College, Glasgow, established an international reputation for teaching and research. It seems appropriate, therefore, that the recently completed first phase of a long-term scheme of development of the College which, since 1956, has been called the Royal College of Science and Technology, should be a new building for engineering. The College is one of the leading technological institutions in Britain selected for major expansion in accordance with the national plan for higher technological education. It has been affiliated to the University of Glasgow for some forty-five years and was recognized as a university college in 1919.

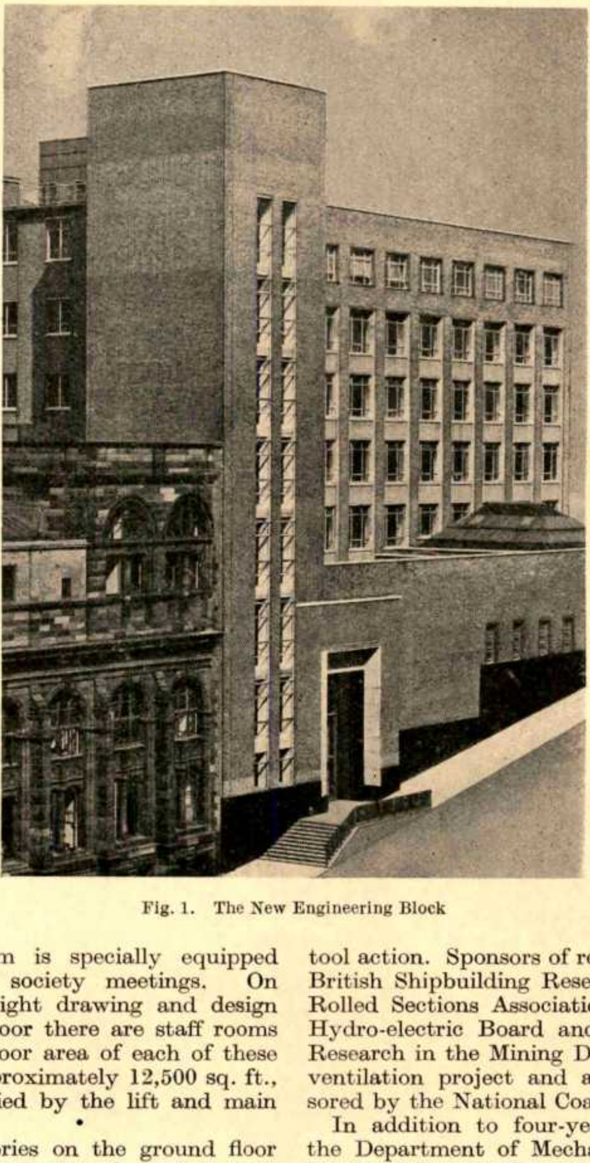

Fig. 1. The New Engineering Block

The new building accommodates the Department of Mechanical, Civil and Chemical Engineering and the Department of Mining. It is a seven-story building adjoining the older buildings of the College. The laboratories containing heavy equipment are housed on the ground floor, which extends beyond the line of the upper floors. Smaller teaching and research laboratories occupy the first floor. The second floor accommodates fourteen rooms which can be used as lecture rooms, small laboratories or research rooms, as required. The Mining Department occupies the whole of the third floor and, in addition, has a laboratory in the basement of the building. The main lecture rooms are on the fourth floor and are eight in number; one of them is specially equipped for general lectures and society meetings. On the fifth floor there are eight drawing and design offices, and on the sixth floor there are staff rooms and central offices. The floor area of each of these floors above the first is approximately 12,500 sq. ft., excluding the space occupied by the lift and main stairway.

The eight large laboratories on the ground floor are equipped for teaching and research work in connexion with hydraulic structures and concrete, hydraulic machines, static testing of materials and components (loads up to 250 tons), dynamic testing of materials and components together with hardness testing and the compression testing of masonry, production engineering, aerodynamics, machine dynamics and heat engines, respectively. Thus, the production engineering or machine tool laboratory contains a variety of modern machine tools such as lathes, milling machines and grinding machines. The equipment of the aerodynamics laboratory includes wind tunnels, while that of the machine or technical dynamics laboratory includes electrical and hydraulic servo mechanisms and an analogue computer, in addition to equipment for studying vibrations and balancing of machinery. Smaller laboratories on the first and second floors are equipped for advanced teaching and research in soil mechanics, theory of structures and experimental stress analysis, chemical engineering and metrology, as well as for teaching elementary mechanics of machines, dynamics, statics and strength of materials and hydraulics.

A variety of research projects is being conducted in the laboratories, and facilities are provided to enable students to work for higher degrees. Notable among the research activities are: hydraulic studies using scale models, contact pressure on foundations, non-destructive testing of concrete, circulation in water-tube boilers, transportation of solids by fluids, corrosion fatigue of steel in sea-water, load-carrying capacity of thin-walled structures, behaviour of shell structures, transients in heat transfer and cutting tool action. Sponsors of research projects include the British Shipbuilding Research Association, the Cold Rolled Sections Association, the North of Scotland Hydro-electric Board and the Ministry of Supply. Research in the Mining Department includes a mine ventilation project and a subsidence project sponsored by the National Coal Board.

In addition to four-year undergraduate courses, the Department of Mechanical, Civil and Chemical Engineering provides one-year and evening post-graduate courses for practising engineers, the subjects of which include nuclear power, production engineering, structural engineering and environmental control engineering.

SOME NEW OXFORD BOOKS

A History of Technology

Volume IV : The Industrial Revolution c. 1750 *to* 1850.

Edited by CHARLES SINGER, E. J. HOLMYARD, A. R. HALL, *and* TREVOR I. WILLIAMS

This *History*, to be completed later in the year by the issue of the fifth volume, covers the subject from the Old Stone Age to the later nineteenth century, and the first three volumes (price £8. 8s. net each) have been enthusiastically reviewed. The illustrations, many of them specially drawn, are a feature of the work. 48 *half-tone plates*, 350 *text-figures.* £8. 8*s. net*

The Origin of Species

By Means of Natural Selection or *The Preservation of Favoured Races in the Struggle for Life*

CHARLES DARWIN

A reprint of the SIXTH EDITION *with a Preface by* SIR GAVIN DE BEER

This is the only sixth edition available today, and is preferred because it was the last to be overseen by Darwin himself.
(*The World's Classics*) 7*s. net*

Electric Conduction in Semiconductors and Metals

W. EHRENBERG

A textbook for students, research workers, and engineers who possess a good grounding in physics and desire to acquaint themselves with the electrical properties of semiconductors and the underlying theory. 63*s. net*

Experimental Crystal Physics

W. A. WOOSTER

'A noteworthy feature is the clarity of the author's style, which makes the book surprisingly easy to read. It is clearly printed and reasonably priced, and will be of much value to university teachers who organize courses in practical physics, and to their students.' *The New Scientist* 18*s. net*

Elementary Coordinate Geometry

E. A. MAXWELL

This book, at sixth-form level, is intended for those who hope to become mathematical specialists. Parametric representation, the use of determinants, and the links between calculus and coordinate geometry are all exploited but not overworked. There is an additional chapter on the general conic.
Second edition 25*s. net*

A Modern Approach to Organic Chemistry

J. PACKER *and* J. VAUGHAN

With a Foreword by C. K. INGOLD

The emphasis in this book, which covers basic requirements for an initial degree, is given to the correlation of theory with fact. The authors have amassed the knowledge acquired in this field during the last thirty years, and the work may be considered comprehensive. 84*s. net*

An Introduction to Chemical Thermodynamics

E. F. CALDIN

In discussing the laws of thermodynamics, the author has aimed at a balanced account of the experimental evidence, the methods of handling it, and the interpretation of results. University students will find the book useful for undergraduate or graduate course work. 50*s. net*

Oxford
UNIVERSITY PRESS

ANALYTICAL CHEMISTRY in the USSR

a comprehensive review in complete translation

A special 40th Anniversary issue of the **Journal of Analytical Chemistry of the USSR** (*Zhurnal Analyticheskoi Khimii*), published in September-October, 1957, is now completely translated, and provides a concise and comprehensive review of the development and current status of research in analytical chemistry in the Soviet Union.

eleven review papers

Development of research on analytical chemistry in the U.S.S.R.
Application of radioactive isotopes in analytical chemistry.
Electrochemical methods in analytical chemistry.
Extraction methods for separation of elements.
The analytical chemistry of the actinoids.
Inorganic microchemical analysis.
Photometric methods of analysis.
Chromatographic analysis.
Spectrographic analysis.
Radiometric methods.
Organic reagents.

special reduced price

Because of the significance of this issue as an up-to-date review of Soviet analytical chemistry, and as an introduction to our complete English translation of the **Journal of Analytical Chemistry of the USSR**, we are making available copies of this special anniversary issue at only $10.00—half the usual pre-issue price. Purchasers of this special issue may subsequently apply the purchase price toward a subscription to the 1957 volume of this continuing journal translation.

The translation, of course, is by Consultants Bureau's bilingual analytical chemists, complete with all tabular material, photographs, and diagrams.

Special Anniversary Issue, J. Anal. Chem. USSR	$10.00
Yearly subscription to complete English Translation, Journal of Analytical Chemistry of the USSR (6 issues per year)	$80.00

Request information re payment in sterling.

Oliver & Boyd

EDINBURGH : TWEEDDALE COURT LONDON : 39a WELBECK STREET

The Upper Atmosphere

H. S. W. MASSEY & R. L. F. BOYD

An account of the phenomena of the upper atmosphere studied during the International Geophysical Year. The subjects covered include aurorae, cosmic rays and probing by rockets and artificial satellites.
Fully illustrated in colour, monochrome and line. [63s.]

Everyday Meteorology

A. AUSTIN MILLER & M. PARRY

Explains the science of the weather and its importance to the community. The emphasis is on the weather we experience, but it is not a manual of weather observing. Special prominence is given to the concepts of 'air masses' and 'fronts'. *Fully illustrated with diagrams and photographs.* September 22nd [30s.]

The Geological Drama

H. TERMIER & G. TERMIER

Describes a modern theory of the formation of the continents and the manner in which geology and biological evolution are inter-related. It is not a conventional historical geology.
Fully illustrated in half-tone and line. [30s.]

Man's Journey Through Time:

An Introduction to Anthropochronology

L. S. PALMER

Professor Palmer shows how man's physical evolution and cultural development may be expressed quantitatively and graphed against the accepted time-scale of the last million or so years. An extrapolation of the observed trends into the future is then suggested. [30s.]

W. Heisenberg

THE PHYSICIST'S
CONCEPTION OF NATURE

The author writes, 'I have tried to give a brief sketch of the problems confronting modern man because of the changes in the world-view of physics and science.' [16s.]

Hutchinson
SCIENTIFIC & TECHNICAL

Blackie

Physical Optics

DR. R. A. HOUSTOUN

This book is intended for students who have reached the Intermediate Science Standard in physics and who are proceeding further with the study of light.
40s. ***net***

Atomic Physics

MAX BORN, F.R.S.

A lucid and up-to-date account of the physics of the atom, and of the various forms of the quantum theory. In the *Sixth Edition* the changes are of detail and experimental data rather than changes in theoretical conceptions.
40s. ***net***

Theoretical Physics

PROF. GEORG JOOS

This *Third Edition* has been thoroughly revised by Dr. Freeman, working in collaboration with Dr. Joos. The whole field of Applied Mathematics and Theoretical Physics, classical and modern, is covered on a level suitable for the student taking an Honours course in Physics.
70s. ***net***

A Structural Introduction to Chemistry

E. T. HARRIS

A simple but accurate introduction to chemistry by describing in turn the structure of atoms, molecules, elements and compounds, with some explanation of the energy relations between them and the consequent chemical changes.
12s. 6d. ***net***

Practical Microscopy

(NEW THIRD EDITION)

MARTIN AND JOHNSON

The practical techniques of microscopy are emphasized throughout. The theory of the optical system is given concisely. Modern trends are indicated, such as the use of ultra-violet light, interference, and electron microscopy.
12s. 6d. ***net***

New Books

SCIENCE IN SCHOOLS

Edited by W. H. PERKINS, O.B.E.,
for the British Association for the Advancement of Science

Learning before luxury ? Should schools receive a better share of the scientists who are graduating to-day ? Science as an also-ran in girls' grammar schools ? " Just one period a week of nature study " for primary school science ? How are we spending now . . . how much . . . how quickly should we expand ?

These and other topical questions on science education were discussed by certain leading industrialists, scientists and educationalists of our day at the April 1958 British Association Meeting. The papers now appear in eminently readable book-form. They will be of interest to all who believe that the development of science and technology cannot take place without a much bolder programme of rapid educational advance than any which has yet been promulgated.

Price 15*s*.

THEORETICAL ELECTROMAGNETISM

By W. R. MYERS, M.Sc., A.Inst.P.
University of Southampton

The aim of this work is to provide a concise introduction to the essentials of electromagnetic theory, together with a few examples of its application. The book is designed for undergraduates reading for an honours degree in physics and the author assumes the reader to be familiar with electricity and magnetism up to the standard of Intermediate B.Sc., or Advanced level G.C.E. examinations.

Mathematically the treatment has been kept simple but the use of vector methods is essential. The four-dimensional Giorgi system of units has been adopted and to assist those who are accustomed to a three-dimensional system, a table of units and conversion factors for electrical quantities is included. A selection of worked examples in electrostatics is given at the end of the book.

Price 42*s*.

BIBLIOGRAPHY OF FOOD

By E. ALAN BAKER, A.L.A.
Librarian, Ministry of Food, 1949–55
and D. J. FOSKETT, M.A., F.L.A.
Information Officer, Metal Box Co., Ltd., 1948–57

This bibliography sets out to demonstrate the wealth of material available to the food chemist and the food scientist. International in scope, it includes most of the significant works of authors on nutrition, food economics and food technology published in the English language, together with a representative selection of material from most foreign sources. Indeed, foreign literature coverage amounts to 30 per cent.

Only published material has been included. Material prepared privately by research and other organizations has not been listed, though the names and addresses of such organizations are included, giving added value to the work as a modern directory for the Industry. The book forms an essential reference tool for all engaged in work on nutrition, food and drink processing, food technology, distribution, packaging, economics, and the legal aspects of the food industry.

Price 63*s*.

PITMAN

Parker St., Kingsway, London, WC2

READINGS IN LINEAR PROGRAMMING

By S. Vajda, Ph.D. Linear programming is a mathematical computing technique developed during the last decade and it is an important tool of the operational research worker. This book contains examples of the practical application of this technique. 20s. net.

MYCOSES OF MAN AND ANIMALS

By R. Vanbreuseghem, M.D. Translated by J. Wilkinson, Ph.D., F.L.S. A translation of Professor Vanbreuseghem's revision of Dr. Langeron's famous work—*Précis de Mycologie.* The various mycoses—their causes, diagnosis, treatment, etc.—are described and recent progress in the field is included. 50s. net.

PERFORMANCE AND DESIGN OF A.C. COMMUTATOR MOTORS

By E. Openshaw Taylor, B.Sc., etc. Written as a companion volume to Clayton's *Performance and Design of D.C. Machines* and Say's *Performance and Design of A.C. Machines.* By including in this new work the single-phase induction motor the three books thus cover the whole range of electrical machinery. 45s. net.

BRITISH FERMENTATION INDUSTRIES

(Other than Brewing and Antibiotics)

By J. H. Whitmarsh, M.Sc., A.R.I.C. Describes fermentation processes likely to be encountered in this country. It covers preparation of industrial alcohol, vinegar, yeast, citric acid, riboflavin, etc. Approx. 25s. net.

PRESTRESSED CONCRETE

By P. B. Morice, B.Sc., Ph.D., etc., and E. H. Cooley, M.A.(Cantab.), etc. This book collects together the more important aspects of structural analysis, design, and current practical procedures of prestressed concrete. The information is presented in a textbook style and the material introduced directly without a discursive approach. 57s. 6d. net.

A GUIDE TO NUCLEAR ENERGY

By Major-General R. F. K. Belchem. A useful production for technical and commercial executives and students who need a basic knowledge of nuclear power. It explains in a simple way the theory of nuclear reaction and the way in which nuclear reactions function. 10s. net.

E. & S. LIVINGSTONE, LTD.

THE INTERFERENCE MICROSCOPE IN BIOLOGICAL RESEARCH
By ARTHUR J. HALE, M.B., Ch.B., Ph.D.
128 pages. 112 illustrations. **20s.**

EXTERNAL COLLIMATION DETECTION OF INTRACRANIAL NEOPLASIA WITH UNSTABLE NUCLIDES
By G. M. SHY, M.D., M.R.C.P., R. B. BRADLEY, B.S., and W. B. MATTHEWS, Jr., B.S.
152 pages. 108 illustrations. **30s.**

CARCINOMA OF THE LUNG
Edited by J. R. BIGNALL, M.A., M.D., M.R.C.P.
310 pages. 69 illustrations. **55s.**
The first volume in a new series of monographs on "Neoplastic Disease at Various Sites" under the general editorship of Professor D. W. Smithers.

ENDOCRINE ASPECTS OF BREAST CANCER
Proceedings of a Conference held in Glasgow, July, 1957
Edited by A. R. CURRIE, B.Sc., M.B., F.R.C.P.(Ed.)
356 pages. 105 illustrations. **37s. 6d.**

THE CLINICAL APPLICATION OF HORMONE ASSAY
By JOHN A. LORAINE, M.B., Ph.D., M.R.C.P.(Ed.)
378 pages. 66 illustrations. **30s.**

LEPTOSPIROSIS IN MAN AND ANIMALS
By J. M. ALSTON, M.D., F.R.C.P.(Ed.), and JOHN C. BROOM, O.B.E., M.D.
330 pages. 40 illustrations. **40s.**

THE UFAW HANDBOOK ON THE CARE AND MANAGEMENT OF LABORATORY ANIMALS
Second Edition. Edited by A. N. WORDEN, M.A., B.Sc., M.R.C.V.S., F.R.I.C., and W. LANE-PETTER, M.A., M.B., B.Chir.
972 pages. 339 illustrations. **70s.**

TEVIOT PLACE, EDINBURGH

THE JOURNAL OF BIOPHYSICAL AND BIOCHEMICAL CYTOLOGY

This new publication of The Rockefeller Institute is edited by Richard S. Bear, H. Stanley Bennett, Albert L. Lehninger, George E. Palade, Keith R. Porter, Francis O. Schmitt, Franz Schrader, and Arnold M. Seligman.

The purpose of the *Journal* is to provide a common medium for the presentation of morphological, biophysical, and biochemical investigations on cells, their components, and the function of these components.

Articles may be submitted in either French, German, or English and should in general be limited in length to 20 printed pages. Short notes of 1,500 words or less on preliminary findings also are accepted. Manuscripts should be sent to the Editors of *The Journal of Biophysical and Biochemical Cytology,* The Rockefeller Institute, New York 21, N.Y.

The *Journal* is issued bimonthly, six numbers constituting a volume. The price is $7.50 per volume and there is no extra charge for domestic or foreign postage. Orders should be addressed to *The Journal of Biophysical and Biochemical Cytology,* The Rockefeller Institute, New York 21, N.Y.

The current issue is Vol. 4, No. 5, September, 1958.

SCIENTIFIC BOOKS

H. K. LEWIS can supply from stock or to order works in all branches of Pure and Applied Science. Catalogues on request.

CONTINENTAL AND AMERICAN works obtained to order at the most favourable rates, with the least possible delay.

SECOND-HAND SCIENTIFIC BOOKS
An extensive stock of books in all branches of Pure and Applied Science may be seen in this department. Large and small collections bought. Back volumes of Scientific Journals.

SCIENTIFIC LENDING LIBRARY

Annual Subscription from £1 17s. 6d. *Prospectus post free on request.*

THE LIBRARY CATALOGUE, revised to December 1956. Pp. xii + 1178. To Subscribers £1 5s. net, to Non-subscribers £2 2s. net; postage 2s. Bi-monthly List of New Books and new editions added to the Library sent post free to subscribers regularly.

recommended for the back room bookshelf

Here is a publication dealing with three types of equipment of first importance to every electronics laboratory. We bring it to your notice because we believe the instruments described and illustrated in it are substantially better in design, performance and finish than anything in their class. They ought to be, because we produce them in a section of our organisation that is solely devoted to the design and manufacture of laboratory electrical equipment. We promise you that you will find this book interesting and useful. Send for a copy now—it's free for the asking.

SIEMENS EDISWAN

laboratory electrical equipment

CRC 17/3

SAUNDERS BOOKS

Routh's 20th CENTURY CHEMISTRY

New (2nd) edition.

By JOSEPH I. ROUTH, *Professor of Biochemistry, University of Iowa.* 613 pages, illustrated. 45s. 6d.

Noller's TEXTBOOK OF ORGANIC CHEMISTRY

New (2nd) edition.

By CARL R. NOLLER, *Professor of Chemistry, Stanford University.* 654 pages, illustrated. 49s.

Designed for a standard first-year course in organic chemistry, this text maintains the same excellent balance between theoretical and practical aspects found in Noller's longer volume.

Bogert's FUNDAMENTALS OF CHEMISTRY

New (8th) edition.

By L. JEAN BOGERT, Ph.D. 615 pages, 168 illustrations. 38s. 6d.

Giese's CELL PHYSIOLOGY

By ARTHUR C. GIESE, *Professor of Biology, Stanford University.* 534 pages, illustrated. 70s.

The first real undergraduate textbook giving exclusive coverage of Cell Physiology.

Villee, Walker & Smith's GENERAL ZOOLOGY

By CLAUDE VILLEE, *Harvard University*; and WARREN F. WALKER and FREDERICK E. SMITH, *University of Michigan.* 877 pages, 444 illustrations. 52s. 6d.

A new book that skilfully correlates " Principles " and " Animal Types " approaches to zoology.

Noller's CHEMISTRY OF ORGANIC COMPOUNDS

(2nd) edition.

By CARL R. NOLLER, *Professor of Chemistry, Stanford University.* 978 pages, 106 illustrations. 63s.

A really superb textbook for a basic course in organic chemistry.

Spector's HANDBOOK OF BIOLOGICAL DATA

584 pages, 52s. 6d.

and **HANDBOOK OF TOXICOLOGY**

Vol. 1. Acute Toxicities of Solids, Liquids and Gases. 49s.

Vol. 2. Antibiotics. 42s.

Edited by WILLIAM S. SPECTOR, *Executive Secretary, Committee on the Handbook of Biological Data, National Research Council.*

THERMOSTATIC OVENS

GOOD PERFORMANCE AT LOW PRICES from £26 COMPLETE

MODELS ALSO MADE TO CUSTOMERS' REQUIREMENTS

In addition to our standard 12 in. × 12 in. × 14 in. Laboratory Ovens (illustrated), we now make a large range of several types of Oven mainly to customers' own specifications. These Ovens are, in general, constructed from marinite insulating panels in a light steel-angle framework and, for baking, are fitted with steel enclosed heaters. We also make Drying Ovens with internal fans for re-circulating air, and complete with inlet and outlet controls. Usual temperature range is up to 200° C. or 250° C.; present maximum internal size is a 30 in. cube.

As a guide we give below a few examples of Special Ovens we have made:

BAKING OVENS	Marinite construction. 18 in. × 18 in. × 18 in. internal dimensions. 30–150° C.	£45
	24 in. × 24 in. × 30 in. 30–150° C.	£75
DRYING OVENS	Marinite Construction and complete with Internal Fan	£35
INCUBATORS	from £26	

Let us know your Oven Needs and we will quote you.

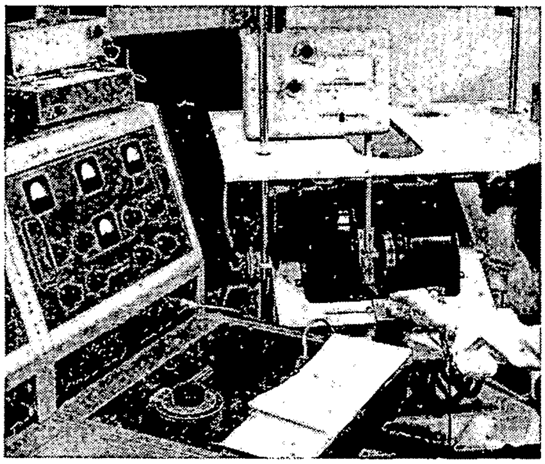
HOW TO "SEE" AND "FOLLOW" UNPAIRED ELECTRONS

15
E-P-R
AT WORK

through EPR spectroscopy, they pinpoint conditions on a molecular scale

(Electron Paramagnetic Resonance)



EPR spectroscopy provides the scientist with a singularly exclusive "sense." It searches the specimen and sees unpaired electrons and their environmental interactions. These may be observed in many forms: free radicals — biradicals — triplet electronic states — transition element ions — semi-conductor impurities — radiation damage sites or color centers.

Interpretation of the EPR spectrum through the location and intensity of resonant peaks can often reveal quantity and identity of the unpaired electrons as well as information about the surrounding molecular structure. To assist the study of chemical kinetics, EPR spectra can be made under varying temperature and chemical environment.

In addition to manufacturing EPR spectrometers and accessories, Varian Associates maintains a staff of scientists experienced at EPR techniques and able to advise on diverse applications.

Number 15 of a series

FREE RADICALS BY IRRADIATION

DISCUSSION: When most organic materials are subjected to high energy ionizing sources the result is a breakdown in the molecule and a production of free radicals. This breakdown generally takes place through the emission of one or more hydrogen atoms from the molecule. The free radicals formed are for the most part extremely unstable. Their stability seems to be dependent upon their mobility. This stability is enhanced, however, if the irradiation is carried out in the solid state. This state is naturally achieved in many solid organic materials but can be achieved in many gases or liquids by freezing them at liquid nitrogen or helium temperatures and irradiating the solids so produced. Free radicals can be identified from their hyperfine pattern, which results from a coupling of the free electron to some other magnetic nuclei in the molecule. Such an identification can serve to locate the site of damage in the molecule being irradiated.

Figures 1 and 2 are examples of free radicals produced by irradiation with a Varian 18 m.e.v. linear accelerator. Figure 1 is the EPR spectrum of irradiated L-Glutamic acid. In this case the free radical is stabilized in the naturally occurring solid amino acid. The hyperfine pattern shows a strong triplet typical of a CH_2^+ radical of ~ 24 gauss separation with 2 or more lines superimposed upon the triplet of about 56 gauss separation which could be due to another free radical in the system. Figure 2 is an example of a free radical stabilized by freezing in liquid nitrogen. The spectrum is that of irradiated methyl alcohol, in which the alcohol was placed in a quartz tube and frozen in a 15 ml. dewar filled with liquid nitrogen. The electron beam was then pulsed through the dewar and quartz tube at about 2 pulses per second for 25 seconds. Once more the strong triplet is observed with a coupling constant of about 18 gauss and another possible doublet with a separation of about 135 gauss. Again this could conceivably be due to a CH_2^+ radical and some other radical.

(*Continued from page* 572)

It was observed that injuries to the brain of the graft as well as the host were far more serious than in homografts; they deserve careful study in both cases, but especially in homografts, because some of the grafted chicks hatch. Deformities and imperfections affecting the upper jaw were also quite common. This particularly applies to the duck-to-chicken transplants, where an under-developed or even vestigial upper bill was a regular occurrence. Deficiencies in the cartilage and bone-forming tissues were pronounced and resulted in an incomplete skull. Another interesting observation is that incubation periods lasting several days more than the normal were recorded. Thus the incubation period of one grafted chicken embryo lasted for 26 days and of a duck embryo for 33 days; both embryos showed a considerable lag in development.

SYNTHESIS OF DEOXYRIBONUCLEIC ACID IN EXTRACTS OF MAMMALIAN CELLS

By Prof. J. N. DAVIDSON, Dr. R. M. S. SMELLIE, Dr. H. M. KEIR and A. HOPE McARDLE
Department of Biochemistry, University of Glasgow

STUDIES on the incorporation of radioactive precursors, such as ^{14}C-formate, ^{14}C-adenine and ^{32}P-phosphate, have shown that Ehrlich mouse ascites tumour cells can synthesize deoxyribonucleic acid under *in vitro* conditions[1]. A more specific precursor of deoxyribonucleic acid, however, is thymidine, which in the form of ^{15}N-thymidine[2], or ^{14}C-thymidine[3], has been shown to be incorporated readily into deoxyribonucleic acid in the rat[2], the chick embryo[3], bone marrow cells[4], isolated thymus nuclei[4], onion root tips[5], and tissue cultures[6]. With the production of thymidine labelled with tritium[7], a new tool has become available for the study of the biosynthesis of deoxyribonucleic acid, and tritiated thymidine has been used by several groups of workers both in the study of chromosome reproduction[7,8] and in the investigation of the formation of deoxyribonucleic acid in regenerating rat liver[9].

Tritiated thymidine obtained from Schwarz Laboratories, Inc., was added to a suspension of Ehrlich ascites tumour cells incubated *in vitro* for 2 hr. in ascitic fluid and the cells processed by methods previously employed[1]. The deoxyribonucleic acid-protein precipitated by perchloric acid from the alkaline digest was treated with 0·5 *N* perchloric acid at 70° for 20 min. to extract the deoxyribonucleic acid, and the extract, after neutralization with potassium hydroxide and removal of potassium perchlorate, was used for determination of deoxyribonucleic acid by measurement of the extinction at 268 mμ in the Beckman spectrophotometer and for assay of tritium in a windowless flow counter.

The tumour cells incorporate (4-^{3}H) thymidine readily into the deoxyribonucleic acid (Table 1). When the cells (including the nuclei) are disrupted in 0·25 *M* sucrose-phosphate buffer by means of an ultrasonic generator[10] the suspension of cellular debris still shows good, though diminished, incorporation. On centrifugation of this material, higher activity is found in the supernatant fluid than in the sediment, and the high activity of the supernatant fluid persists after all particulate matter has been removed by high-speed centrifugation ('Spinco' ultracentrifuge) at 105,000 *g* (Table 1).

Table 1. Incorporation of (4-^{3}H) Thymidine into the Deoxyribonucleic Acid of Intact and Sonically Disrupted Preparations of Ehrlich Ascites Tumour Cells

The incubations were, for 2 hr., in a medium containing 0·25 *M* sucrose, 0·1 *M* phosphate buffer *p*H 7·4, 2·5 μmoles/ml. adenosine triphosphate, 2·5 μmoles/ml. diphosphopyridine nucleotide, 50 μmoles/ml. glucose 2 μc./ml. (4-^{3}H) thymidine, 4 μmole/ml. magnesium chloride and, 20 μmole/ml. sodium chloride

Fraction	Specific activity of deoxyribonucleic acid (counts/min./μmole deoxyribonucleic acid-phosphorus)
Intact ascites cells	9,700
Sonically disrupted cells	600
Supernatant fraction (1,000 *g*) from disrupted cells	1,225
Sediment	322
Supernatant fraction after high-speed centrifugation (105,000 *g*)	1,661

Although we have used mainly a buffered solution containing 0·25 *M* sucrose and 0·1 *M* phosphate for the preparation of extracts of disrupted cells, other buffers such as Krebs–Ringer phosphate[11] or simple 0·1 *M* phosphate buffer with added magnesium chloride are also effective. The optimum *p*H is in the region of 8.

For good incorporation of ^{3}H-thymidine into deoxyribonucleic acid, adenosine triphosphate, diphosphopyridine nucleotide and glucose are necessary (Table 2). Adenosine triphosphate and diphosphopyridine nucleotide produce their maximum effect at concentrations not less than 2·5 μmoles/ml., while glucose is most effective at the relatively high concentration of 50 μmoles/ml. It may be replaced by other energy sources such as hexose diphosphate, but not by pyruvate or glutamate.

Table 2. Incorporation of (4-^{3}H) Thymidine into the Deoxyribonucleic Acid of a Particle-free Extract of Disrupted Ascites Cells in 0·1 *M* Phosphate Buffer *p*H 8 containing 4 μmoles/ml. Magnesium Chloride, 20 μmoles/ml. Sodium Chloride and 4 μc./ml. (4-^{3}H) Thymidine

Additions to extract (μmole/ml.)			Specific activity of deoxyribonucleic acid (counts/min./μmole deoxyribonucleic acid-phosphorus)
Adenosine triphosphate	Diphosphopyridine nucleotide	Glucose	
2·5	2·5	50	8,230
0	2·5	50	262
2·5	0	50	1,550
2·5	2·5	0	1,700

Other tissues, such as chick embryo, on sonic disruption in sucrose–phosphate buffer also yield active extracts, but none has proved so effective as ascites cells. Examination of cell-free extracts from a series of rabbit tissues disrupted sonically shows that the potency of an extract varies according to the mitotic activity of the tissue from which it is derived (Table 3). These extracts have been obtained by the complete disruption of the cells, including the nuclei. A potent extract of chick embryo has also been obtained by gently homogenizing chick embryonic tissue in sucrose–phosphate buffer, centrifuging down the cell debris, including the nuclei, and subjecting the supernatant fluid to high-speed centrifugation so as to remove mitochondria and microsomes.

Table 3. INCORPORATION OF (4-^{3}H) THYMIDINE INTO DEOXYRIBONUCLEIC ACID BY PARTICLE-FREE EXTRACTS OF DISRUPTED RABBIT TISSUES AND CHICK EMBRYOS

Incubation conditions were as in Table 1 except that the (4-^{3}H) thymidine concentration was 5 μc./ml. and *p*H was 8

Tissue	Specific activity of deoxyribonucleic acid (counts/min./μmole deoxyribonucleic acid-phosphorus)
Rabbit bone marrow	2,450
Rabbit appendix	886
Rabbit liver	545
Rabbit kidney	505
Chick embryo	1,865

These findings with different tissues are in accordance with the observations of Friedkin and Wood[4] with tissue slices incorporating ^{14}C-thymidine and with our own previous findings on the incorporation of ^{32}P-phosphate, ^{14}C-formate and ^{14}C-adenine in rabbit tissues *in vivo*[12].

Evidence that the material into which the tritiated thymidine is incorporated is deoxyribonucleic acid is provided by the observations that it is insoluble in acid, precipitated by acid after alkaline incubation, can be isolated as deoxyribonucleic acid which on hydrolysis yields the expected four bases of which the thymine alone is radioactive, and is broken down by deoxyribonuclease to yield acid-soluble radioactive fragments. Moreover, when the radioactive deoxyribonucleic acid is degraded by the diphenylamine method[13], radioactive thymidine-3′ : 5′-diphosphate has been isolated after ionophoresis of the reaction products, as well as other radioactive components showing the spectral and mobility characteristics which would be expected of oligonucleotides containing both thymine and cytosine.

It is impossible at this stage to determine whether the incorporation of tritiated thymidine consists merely of the addition of a terminal nucleotide (or nucleotides), or whether the thymidylic acid is to be found in the body of the polynucleotide chain (both processes are known to take place in relation to incorporation of ribonucleotides into ribonucleic acid by cell-free systems[14]) ; but if, as appears probable, the incorporation of ^{3}H-thymidine is due to true synthesis of deoxyribonucleic acid, it must be assumed that the remaining three nucleotides are provided from the small pool of deoxynucleosides and deoxynucleotides which is known to exist in mammalian tissues[15]. Biosynthesis would then proceed by two major steps, the phosphorylation of the nucleosides and the assembly of the phosphorylated products into the polynucleotide chain. Although the bacterial polynucleotide phosphorylase of Ochoa[16] utilizes ribonucleoside diphosphates in the formation of ribopolynucleotides, the work of Kornberg[17] with bacterial systems suggests that the deoxynucleoside triphosphates are required for synthesis of deoxyribonucleic acid. The ability of mammalian enzymes to phosphorylate deoxynucleotides has already been demonstrated with kidney mitochondria[18], rat liver homogenates[19] and bone marrow extracts[20], and our extracts of sonically disrupted ascites cells have been found capable of converting deoxyribonucleoside monophosphates to the triphosphate stage (Keir, H. M., and Smellie, R. M. S., unpublished results).

It is clear that our system is similar to the systems found in regenerating rat liver by Bollum and Potter[9] and by Mantsavinos and Canellakis[21] for the incorporation of ^{3}H-thymidine[9] or ^{14}C-deoxynucleotides[21] into deoxyribonucleic acid, although the conditions employed by these authors are rather different from ours. Both groups found that the addition of primer deoxyribonucleic acid greatly stimulated incorporation. In our system this is not essential, since the crude particle-free extract of disrupted ascites cells already contains measurable amounts of deoxyribonucleic acid and a substantial quantity of ribonucleic acid, but addition of carrier deoxyribonucleic acid greatly increases incorporation.

These investigations have been aided by grants from the Medical Research Council, the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research and the Anna Fuller Fund, all of which are gratefully acknowledged.

PREPARATIVE-SCALE GAS CHROMATOGRAPHY

By Dr. D. E. M. EVANS, W. E. MASSINGHAM, Prof. M. STACEY, F.R.S.,
and Dr. J. C. TATLOW

The Chemistry Department, The University, Edgbaston, Birmingham 15

ANALYTICAL gas chromatography has been studied extensively during the past few years and is now used very widely. In this Department[1-5], gas chromatography has been applied also on a preparative scale (1–10 gm.) for the isolation of pure compounds from volatile mixtures which are difficult to separate in other ways. This aspect has apparently received little attention elsewhere, and few such developments are described in the literature[6-8]; it has been suggested, in fact, that any appreciable increase in column diameter would lead to a rapid decrease in efficiency. Consequently, small-scale batch processes have been employed for isolating specimens, using narrow-bore columns[7,8]. In view of the apparent scepticism about the value of the technique on a preparative scale, we wish to direct attention to our work on this type of gas chromatography, independently of the reporting of results in organic fluorine chemistry to which it has been applied. A process of high efficiency, capable of separating complex mixtures of volatile compounds in 1–50gm. quantities in a single cycle, is clearly of great potential importance, particularly if the apparatus is relatively simple. We have developed such equipment, which is used regularly on a routine basis by a large group of research workers.

We have already reported the design[1,2] and use[1-5] of a column having a total length of 16 ft. and an internal diameter of 30 mm., and packed with dinonyl phthalate/kieselguhr. The scaling up of the gas chromatographic process caused no apparent decrease in resolution. A similar column has been operated[4] with a packing of tricresyl phosphate/kieselguhr. We have since constructed an even bigger column, made of hard glass, packed with dinonyl phthalate/kieselguhr (1 : 2), and of the same total length (16 ft.; in two sections, each of 8 ft., joined by a narrow-bore bend) but having an internal diameter of 75 mm. It is mounted horizontally in electrical heaters of a type described before[10]. This column is being operated continuously as a general-purpose fractionating unit of high efficiency by colleagues in our fluorine research group. The cross-sectional area of this column is roughly six times that of the smaller preparative-scale unit, and for a series of separations under similar operating conditions the maximum sizes of samples have been about six times those for the smaller column. The actual quantity of any mixture which may be separated in either type of column depends chiefly on the differences in retention times between the various components present. With the larger unit, if the peaks are well apart, a charge of 50 gm., or even more, may be separated with ease. If the peaks are close, 12–15 gm. will probably represent the optimum quantity. As with all columns, an efficient pre-heater is necessary to volatilize the charge rapidly. Table 1 lists a few separations, typical of many examples with analogous compounds, which have been carried out using the larger column.

The design of the apparatus is essentially the same as that described earlier[1,2]. However, one important modification to the detector unit has been necessary. The sensitivity of katharometer detectors fell rapidly with increasing velocity of the gas. One solution to this problem would have been to use a by-pass system, passing only a small portion of the gas through the detector. However, experiments with such a system showed that in certain cases some mixing occurred in the collecting trap when two peaks which were close together were being eluted, despite the indication of a complete separation by the detector unit. It was found rather troublesome to eliminate this effect completely, and it appeared desirable to pass the total effluent from the column through the detector. Preliminary experiments, using glass katharometers of wide bore, indicated that although a normal signal could be obtained by increasing the diameter of the sensing channel to compensate for the high rates of flow of the carrier

§ Obtained by dehydrofluorination of 1*H* : 2*H* : 4*H* : 5*H*-octafluoro*cyclo*hexanes (ref. 11).

gas used, care was necessary to avoid turbulence if the detector was to remain stable. Accordingly, a katharometer was made from a brass block by cutting in it a streamlined channel with diameter increasing gradually along its length to a maximum of approximately 1 in. and then gradually tapering down, finally terminating in a nozzle of approximately 0·25 in. diameter. In the widest part of the channel were fixed two disks of nickel gauze; between these disks (which were at right-angles to the flow of gas) was screwed an insulated metal former on which was fixed a tungsten spiral. The dead spaces between the disks and the inlet and outlet were packed with glass wool. A similar cell, in the same block, was incorporated in the gas inlet-stream, the resistances of the tungsten wires being the same. The wires form two arms of a d.c. Wheatstone bridge, powered by a 6-V. accumulator, and the out-of-balance potential was fed directly to a recorder (Honeywell-Brown, 0–1 mV.), no further amplification being necessary. A sensitivity control normally run at half the maximum was inserted before the recorder. This system is both sensitive and stable at flow-rates of gas of 50 l./hr., and minor components of the mixtures which are scarcely visible when collected in the traps may be detected with ease.

The collecting traps are of the normal design with a side inlet and central outlet. They are 60 mm. in diameter, and are cooled in liquid oxygen. It is desirable to distil the separated components from the traps *in vacuo*, since trace quantities of the packing material are progressively removed from the column in the gas stream. Recoveries of material of 80–90 per cent are obtained with ease, and if special precautions (for example, the introduction of samples *via* a vacuum line) are taken to avoid handling losses, the recoveries approach 100 per cent.

Theoretical plate determinations on each of the preparative-scale columns and on a typical analytical-scale column showed no apparent fall in efficiency with increase in column diameter. It would appear that even bigger columns could be operated successfully, particularly as more stationary phases become available. It can be seen from our results that as a practical means of separating volatile mixtures, preparative-scale gas chromatography is a remarkably successful technique. Certainly much of the recent work of our fluorine research group would have been very difficult if not impossible to carry out without it.

INCORPORATION OF AMINO-ACIDS BY DISRUPTED STAPHYLOCOCCAL CELLS

By DR E. F. GALE, F.R.S., DR C. J. SHEPHERD
and JOAN P. FOLKES

Medical Research Council Unit for Chemical Microbiology, Department of Biochemistry,
University of Cambridge

IN 1953, Gale and Folkes[1] described a preparation of disrupted cells of *Staphylococcus aureus* which, in the presence of adenosine triphosphate and an energy generating source, was able to incorporate amino-acids into the trichloracetic acid precipitable fraction. Subsequent experiments[2] showed that the course of incorporation of glutamic acid labelled with carbon-14 into this fraction varied with the conditions of incubation. Two conditions in particular were studied: condition 1, in which glutamic acid was the only amino-acid added to the medium; and condition 2, in which a mixture of eighteen amino-acids was added, glutamic acid only being labelled. Under condition 2 the incorporation of glutamic acid continued at a steady rate for several hours and an increase in 'protein'-nitrogen and certain enzymic activities could be demonstrated.* Under condition 1 no significant change in the 'protein' content of the preparation could be measured and the rate of incorporation, initially faster than that under condition 2, decreased rapidly so that incorporation ceased after approximately 60 min. If the disrupted cells were washed free from medium after incorporation under condition 1 had ceased, and then re-incubated in the presence of an energy source and unlabelled glutamic acid, a partial release of the incorporated radioactivity occurred; this release did not take place if the second incubation was carried out in the presence of energy source alone, unlabelled glutamic acid alone, or energy source together with unlabelled glycine or aspartic acid. It was suggested that incorporation under condition 1 could not be taken as a measure of protein synthesis, but that the results were consistent with the hypothesis that the process involved one amino-acid and arose from substitution of corresponding residues in preformed protein by an exchange reaction. Since incorporation under condition 1 could be markedly decreased by removing nucleic acid from the cell preparation, it was further suggested that such exchange reactions involved nucleoprotein complexes.

The trichloracetic acid precipitate obtained from intact or disrupted staphylococcal cells includes cell walls, and it is now known that these walls contain a hexosamine peptide polymer in which glycine, D- and L-alanine, L-lysine and D-glutamic acid are the principal amino-acids[3,4]. The recent demonstrations

Table 1. INCORPORATION OF AMINO-ACIDS INTO THE CELL-WALL FRACTION AND INTO MATERIAL FROM *Staphylococcus aureus* (STRAIN DUNCAN) INSOLUBLE IN HOT TRICHLORACETIC ACID IN INTACT AND DISRUPTED CELL PREPARATIONS

Amino-acid	Specific activity (counts/min./mμmole)	Incorporation in intact cells*		Incorporation in disrupted cells†	
		Counts/min. TCA ppt.	Per cent radio-activity in wall fraction	Counts/min. TCA ppt.	Per cent radio-activity in wall fraction

* Intact cells incubated at 0·5 mgm. dry weight/ml. in phosphate-saline *p*H 7·0 containing 1·5 per cent (w/v) glucose and one of the above amino-acids (L-isomer, generally labelled with carbon-14) at 0·01 μmole/ml. except in cases marked ‡, where amino-acid concentration was increased ten times. Incubation for 60 min. at 37°. TCA ppt. = material from 1·0 mgm. dry weight of cells which is insoluble in hot 5 per cent trichloracetic acid; wall fraction separated by the method of Hancock and Park (ref. 6).

† Disrupted cells (ref. 2) incubated at 0·7 mgm. dry weight/ml. in phosphate–saline *p*H 6·25 containing adenosine triphosphate, hexosediphosphate and one amino-acid as for intact cells.

that intact *Staphylococci* incubated with glucose can incorporate these amino-acids, added either singly or in simple mixtures to the medium, into cell wall structures[5,6] and that incorporation in animal and *Tetrahymena* cells involves a polyribonucleotide component with which amino-acids can combine in a reversible manner[7], make it desirable to re-assess and re-investigate the nature of 'condition 1 incorporation' in the disrupted staphylococcal cell preparation.

Incorporation into the Cell Wall Fraction

Table 1 shows the incorporation of certain amino-acids, each investigated under condition 1 as the only amino-acid added to the incubation medium, into the material insoluble in hot trichloracetic acid and the cell-wall fraction (separated by the method of Hancock and Park[6]) of intact *Staphylococcus aureus* strain Duncan and disrupted cell preparations made from it. With intact cells in the presence of glucose, more than 90 per cent of the glycine and more than 50 per cent of the lysine, alanine and glutamic acid is found in the cell-wall fraction, which may contain part of the cell membrane in addition to the true outer wall. In the disrupted cell preparation, the amounts of the 'wall amino-acids' which are incorporated relative to valine or leucine are smaller, and the proportion residing in the wall fraction markedly less than in the intact cell. It would appear that one result of exposure to supersonic vibration is reduction of the incorporation of amino-acids into the wall structure. The proportion of the incorporated glutamic acid found in the wall fraction varies with the preparation and has ranged from 8 to 35 per cent (mean 19 per cent), for ten preparations. The preparation used in Table 1 was exposed for the time necessary to obtain good depletion of nucleic acid[2]; shorter exposure results in a higher proportion of the incorporated glutamic acid appearing in the wall fraction.

Reversible Incorporation

Whereas the earlier experiments were carried out with material insoluble in trichloracetic acid, the nature of the bound glutamic acid not in the wall fraction has now been investigated by electrophoresis of extracts of the cells on starch columns as described by Pardee, Paigen and Prestidge[8]. After incorporation, the disrupted cell preparation is washed exhaustively in water and then subjected to a further 4-min. exposure to supersonic vibration to disintegrate its structure. The disintegrated material is centrifuged at 5,000 *g* for 30 min. to remove cell-wall fragments, the supernatant material inserted in the starch column and subjected to 600 V./30 cm. for 4½ hr. in 0·05 *M* *tris* buffer at *p*H 7·6. At the end of this period, the column is cut into 1-cm. sections and each section eluted with 5 ml. of water. The nucleic acid content of the eluates is measured by optical density at 260 mμ, the eluates dried and their radioactivity determined. The distribution of radioactivity along the starch columns varies with the conditions of incubation during incorporation.

Fig 1*A* shows that incorporation under condition 2 gives rise to a distribution of glutamic acid such that more than 60 per cent of the radioactivity lies in the slow-moving fractions (moving less than 10 cm. from the origin); if incorporation takes place under condition 1 (Fig. 1*B*), then 70–80 per cent of the radioactivity lies in fast-moving fractions (11–15 cm. from the origin) close to the nucleic acid front. Fig. 1*C* shows that there is no significant alteration in this latter distribution if the disrupted cell preparation is afterwards incubated with the energy source alone or unlabelled glutamic acid alone, but some 50 per cent of the radioactivity is released, and can be recovered from the medium, if the second incubation takes place in the presence of an energy source and unlabelled glutamic acid. No such reversal has been observed in the slow-moving fractions whether incorporation has taken place under condition 1 or 2; the eluates from these fractions have ultra-violet absorption spectra typical of nucleoproteins and their radioactivity is precipitated by 5 per cent trichloracetic acid in the cold.

The nature of the fast-moving fraction which becomes reversibly labelled when incubation takes place with L-glutamic acid under condition 1 is now being investigated. The α-carboxyl group is not attacked by ninhydrin, but 96 per cent of the glutamic acid is released by treatment with 0·01 *N* potassium hydroxide for 5 min. at 30° or *N* hydrochloric acid for 60 min. at 100°. Treatment with ribonuclease releases 30–40 per cent of the glutamic acid. Incubation with L-glutamic acid decarboxylase shows that the glutamic acid is not all in the L-form: 40–45 per cent of that released by acid hydrolysis assays as the L-isomer. 90 per cent of the radioactivity of the eluate from the fast-moving fraction is left in the aqueous phase after shaking with aqueous phenol[7]; addition of trichloracetic acid in the cold to 5 per cent final concentration precipitates less than 2 per cent of the radioactivity. From these results it would appear that the labelled fraction is complex, but the radioactivity is quantitatively eluted from 'Ecteola' cellulose[9] columns by 0·05 *M* *tris* buffer at *p*H 7·6. If the original incubation mixture contains unlabelled glutamic acid but adenine or uracil labelled with carbon-14, the fast-moving fraction and the eluate from 'Ecteola' cellulose become labelled.

When disrupted cell preparations are labelled with glutamic acid under condition 1, washed and then re-incubated under condition 2 in the absence of added glutamic acid, an amount of label ranging from 30 to 50 per cent of the total in the fast-moving fraction is

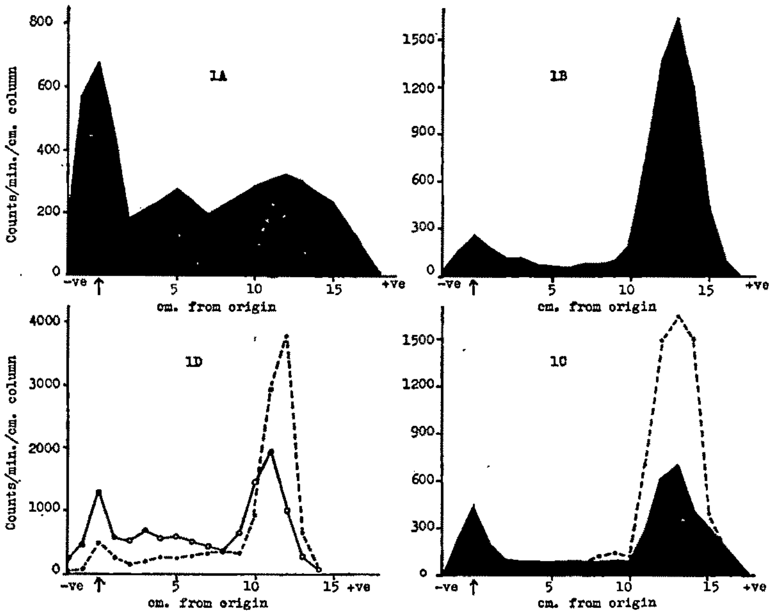

Fig. 1. Distribution, after electrophoresis on starch columns, of radioactivity in extracts from disrupted staphylococcal cells after incubation with glutamic acid labelled with carbon-14, and an energy-generating source

1*A*. Incubation under condition 2 (ref. 2) (18 amino-acids present) with 0·1 μc. glutamic acid (specific activity 0·9 mc./mmole)/ml. for 2 hr. at 37°. Total counts/min. eluted = 5,503 ; extract from approximately 5·5 mgm. dry-weight disrupted cells

1*B*. Incubation under condition 1 (glutamic acid being the only amino-acid added) with 0·1 μc. glutamic acid (specific activity 11·7 mc./mmole)/ml. for 1 hr. at 37°. Total counts/min. eluted = 8,329 ; extract from approximately 2·1 mgm. dry-weight disrupted cells

1*C*. As for 1*B* ; disrupted cell preparation washed after incubation as 1*B* and re-incubated for 1 hr. in the presence of the energy-generating source alone (broken line) or with the addition of 0·4 μmole unlabelled glutamic acid/ml. (solid block). Incubation with unlabelled glutamic acid without energy-generating source gives distribution significantly the same as the broken line. Total counts eluted = 7,894 (broken line), 4,193 (solid block)

1*D*. (i) Broken line : incubation as for 1*B* ; total counts/min. eluted = 11,715 ; extract from approximately 2·6 mgm. dry-weight disrupted cells. (ii) Continuous line : redistribution of activity in (i) obtained after preparation is washed and re-incubated for 1 hr. under condition 2 in absence of added glutamic acid ; total counts/min. eluted = 11,601

Cell extracts run in all cases for 4½ hr. in starch columns at 600 V./30 cm. in 0·05 *M* *tris* buffer *p*H 7·6 ; columns cut into 1 cm. sections, each section eluted in 5 ml. water and dried for radioactivity determinations. Abscissæ = radioactivity of eluates in counts/min. per section

transferred from that fraction to the slower-moving fractions (see Fig. 1*D*). We are at present endeavouring to investigate the relationship of the fast-moving component(s) to "soluble ribonucleic acid"[7] on one hand, and to the uridine-hexosamine-peptides that accumulate when cell-wall synthesis is inhibited by penicillin[4], on the other.

It is now clear that about 75 per cent of the bound ^{14}C-labelled glutamic acid in extracts of disrupted cells after incorporation under condition 1 is not precipitated by hot 5 per cent trichloracetic acid. The trichloracetic acid precipitate of disrupted cells contains the cell-wall fraction and the slow-moving electrophoretic fractions, whereas the bulk of the fast-moving fraction is not precipitable with trichloracetic acid. Reversible incorporation takes place in the fast-moving fraction or certain components of it ; the earlier suggestion that incorporation can occur by exchange reactions involving preformed proteins is therefore no longer tenable. No explanation can be put forward at present for the occurrence of reversible incorporation in the material insoluble in hot trichloracetic acid from disrupted cells previously described, and it may be that trichloracetic acid is not a suitable reagent for investigations with preparations of this description. From the present studies it appears that the main processes occurring during incorporation of glutamic acid under condition 1 result in labelling of the fast-moving electrophoretic components and (in intact cells) incorporation into cell wall structures.

Inhibitors

One of the puzzling results obtained in the course of studies of the inhibition of amino-acid incorporation under condition 1 has been the partial or 'plateau' nature of the inhibition obtained with antibiotics such as penicillin and chloramphenicol[2,10]. It is now clear that such studies, especially when glycine is the amino-acid incorporated, involve at least two series of processes : those leading to protein synthesis, and those leading to cell-wall synthesis. Inhibitors which give a plateau type of inhibition presumably do not affect one of these series, whereas inhibitors, such as aureomycin and certain benzimidazole derivatives[10], which bring about complete suppression of incorporation, must affect both series. Chloramphenicol inhibits protein synthesis[11] but not the synthesis of cell-wall peptides[5, 6]. Its action on the incorporation of glutamic acid into the nucleoprotein extracts of disrupted cells is to prevent incorporation into the slow-moving electrophoretic fractions, whereas the labelling of the fast-moving fraction is not affected. The presence of chloramphenicol during incubation thus effectively converts the distribution obtained under condition 2 (Fig. 1*A*) into that obtained under condition 1 (Fig. 1*B*) and would appear to inhibit the transfer of labelled residues from the fast-moving to the slow-moving fractions.

Incorporation Factors

The removal of nucleic acid from the disrupted cell preparation results in a decrease in its ability to incorporate amino-acids[2] and to synthesize ribonucleic acid[12] ; these properties can be restored by addition to the incubation medium of staphylococcal nucleic acid. The activity of the nucleic acid preparation in restoring amino-acid incorporation is not decreased by digestion with ribonuclease but is released in fractions which were first identified as small polyribonucleotides[13]. It was later found that the activity is due to contaminating substances present in trace amounts and provisionally called "incorporation factors"[14]. A concentrate with incorporation-factor activity has now been prepared[13] ; this preparation promotes the incorporation of a wide range of amino-acids, including those found in cell-wall peptides and others believed to occur in the protein only. The preparation has been routinely assayed by its ability to promote the incorporation of glycine under condition 1. Table 2 shows that the factor preparation stimulates the incorporation of glutamic acid into both protein and cell-wall fractions

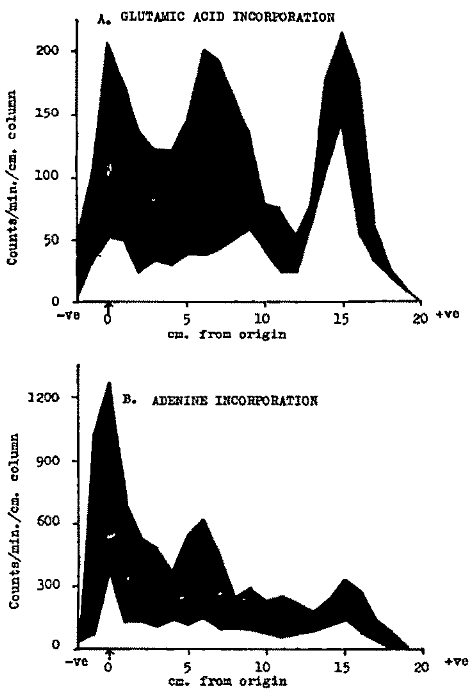

Fig. 2. Distribution of radioactivity, after electrophoresis on starch columns, in extracts of disrupted staphylococcal cells after incubation under condition 2 with (*A*) glutamic acid labelled with carbon-14, and (*B*) adenine, labelled with carbon-14, in the presence and absence of the incorporation factor preparation (ref. 12)

Procedure as for Fig. 1*A* with disrupted-cell preparation first depleted of nucleic acid by incubation with 'Streptodornase' (Lederle). Unshaded portion = incorporation in absence of incorporation factor; black portion = stimulation of incorporation by the presence of the factor preparation. Specific activity of glutamic acid in (*A*) = 0·9 mc./mmole; 103 counts/min. = 1 mμmole. Specific activity of adenine in (*B*) = 8·7 mc./mmole; dilution in course of experiment unknown

of disrupted staphylococcal cells depleted of nucleic acid.

The finding that the incorporation factor preparation is essential for ribonucleic acid synthesis[12] indicates a possible explanation for the apparent replacement of nucleic acid by the factor preparation in studies of amino-acid incorporation. Incorporation of glutamic acid is accompanied by synthesis or turnover of nucleic acid as measured by the labelling of the nucleic acid fraction, precipitable with trichloracetic acid, with adenine, guanine or uracil. Under condition 2, nucleic acid synthesis takes place at a constant rate for several hours, whereas under condition 1 the presence of labelled adenine or uracil and unlabelled glutamic acid shows that there is a limited incorporation of the bases which takes place during the first 30–60 min. of incubation only[12]. Stimulation of glutamic acid incorporation, whether under condition 1 or 2, is accompanied by a similar stimulation of adenine or uracil incorporation, and it may be that the incorporation factor preparation produces its effect on amino-acid incorporation by promoting the formation of nucleotide derivatives rather than by serving as a substitute for the nucleic acid. Fig. 2 shows the electrophoretic distribution of adenine and glutamic acid labels in extracts from disrupted cells depleted of nucleic acid, after incubation under condition 2 in the presence and absence of the incorporation factor preparation. It can be seen that the factor has stimulated incorporation of both adenine and glutamic acid into the nucleoprotein and the fast-moving fractions.

Table 2. STIMULATION OF THE INCORPORATION OF GLUTAMIC ACID BY THE INCORPORATION FACTOR PREPARATION (ref. 12)

	Glutamic acid incorporated (mμ moles)/mgm. disrupted cells		
	Condition 1		Condition 2
	Wall fraction	'Protein' fraction	'Protein' fraction
Disrupted cell preparation depleted of nucleic acid	0·05	0·196	1·50
In presence of 1 mgm. staphylococcal nucleic acid/3·0 ml.	0·35	0·79	6·71
In presence of 1 unit incorporation factor preparation/3·0 ml.	0·30	0·84	7·59

Disrupted cell preparation depleted of nucleic acid by incubation with 'Streptodornase' (Lederle, ref. 12). Incubation conditions as for Fig. 1; condition 1 for 1 hr., condition 2 for 2 hr. 'Protein' fraction = material insoluble in hot 5 per cent trichloracetic acid corrected for wall fraction.

The mechanism of protein synthesis is almost certainly very complex and recent advances have revealed some of the early stages involved in the activation of amino-acids and their reaction with polyribonucleotides and nucleic acids[7]. Similar studies in bacteria are rendered more complicated by the processes leading to the formation of cell-wall peptides, and the crude fractionation procedures so far adopted have given results difficult to interpret since both types of synthesis have occurred in the fractions. The description of methods for the separation of the wall fraction[5,6] represents a welcome advance. The work described here shows that glutamic acid may be incorporated into fractions which are not precipitated by trichloracetic acid even in the cold, and suggests that the syntheses of protein and wall peptides may possess common or similar initial stages. The processes can be dissociated at later stages by the use of inhibitors such as chloramphenicol and penicillin or by treatment with supersonic vibration, although the particular stage at which dissociation occurs is not yet defined in any of these instances. Some of the earlier results[15] with intact *Staphylococcus aureus*, in which incorporation of glutamic acid was relatively unaffected although protein synthesis was inhibited, may be explained in terms of the amino-acid being channelled into wall structures, and it is now necessary to investigate the inter-relationships of wall synthesis and protein synthesis, and to determine to what extent the two processes compete for a common amino-acid under the various experimental conditions that have been studied.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Cancer and Smoking

The curious associations with lung cancer found in relation to smoking habits do not, in the minds of some of us, lend themselves easily to the simple conclusion that the products of combustion reaching the surface of the bronchus induce, though after a long interval, the development of a cancer. If, for example, it were possible to infer that smoking cigarettes is a cause of this disease, it would equally be possible to infer on exactly similar grounds that inhaling cigarette smoke was a practice of considerable prophylactic value in preventing the disease, for the practice of inhaling is rarer among patients with cancer of the lung than with others.

Such results suggest that an error has been made, of an old kind, in arguing from correlation to causation, and that the possibility should be explored that the different smoking classes, non-smokers, cigarette smokers, cigar smokers, pipe smokers, etc., have adopted their habits partly by reason of their personal temperaments and dispositions, and are not lightly to be assumed to be equivalent in their genotypic composition. Such differences in genetic make-up between these classes would naturally be associated with differences of disease incidence without the disease being causally connected with smoking. It would then seem not so paradoxical that the stronger fumes of pipes or cigars should be so much less associated with cancer than those of cigarettes, or that the practice of drawing cigarette smoke in bulk into the lung should have apparently a protective effect.

A letter of mine in *Nature*[1] included a brief first report of some data on the smoking habits of twins in Germany kindly supplied by Prof. v. Verschuer. What was evident in these data, which concerned only males, was that the smoking habits of monozygotic, or one-egg, twins were clearly more alike than those of twins derived from two eggs. The monozygotic twins are identical in genotype and the clear difference in these data gave positive *prima facie* evidence that among the many causes which may influence the smoking habit, the genotype is not unimportant.

Unfortunately, considerable propaganda is now being developed to convince the public that cigarette smoking is dangerous, and it is perhaps natural that efforts should be made to discredit evidence which suggests a different view. Assumptions are put forward which, *if true*, would show my inference from von Verschuer's data not indeed to be false but at least to be inconclusive. I may refer to an anonymous writer "Geminus" in the *New Scientist*[2], who supports in this way "what is rapidly becoming an accepted truth—that smoking can cause lung cancer".

If it could be assumed as known facts (*a*) that twins greatly influence each other's smoking habits and (*b*) that this influence is much stronger between monozygotic than between dizygotic twins, then an alternative explanation would be afforded for the result I have emphasized. The assumptions can be supported by eloquence, but they should, for scientific purposes, be supported by verifiable observations.

Since my letter was written, however, I have received from Dr. Eliot Slater, of the Maudsley Hospital (London, S.E.5), some further data, the greater part of which concern girl twins, and in this way supply a valuable supplement to Verschuer's data, and in which, moreover, a considerable number of pairs were separated at or shortly after birth.

For the resemblance in smoking habit, these female pairs give:

	Alike	Unlike	
Monozygotic	44	9	53
Dizygotic	9	9	18

So far, there is only a clear confirmation of the conclusion from the German data that the monozygotics are much more alike than the dizygotics in their smoking habits. The peculiar value of these data, however, lies in the subdivision of the monozygotic pairs into those separated at birth and those brought up together. These are:

	Alike	Unlike	
Separated	23	4	27
Not separated	21	5	26

Of the nine cases of unlike smoking habit, only four occur among the twenty-seven separated at birth. It would appear that the small proportion unlike among these 53 monozygotic pairs is not to be ascribed to mutual influence.

There is nothing to stop those who greatly desire it from believing that lung cancer is caused by smoking cigarettes. They should also believe that inhaling cigarette smoke is a protection. To believe either is, however, to run the risk of failing to recognize, and therefore failing to prevent, other and more genuine causes.

Density of Acetylene

The literature values for the density of gaseous acetylene are markedly discordant. The principal data, in order of publication, are summarized in Table 1; the values given are at $g = 980\cdot665$ cm./sec.^{2} unless otherwise indicated.

Table 1

Author	Ref.	Density at N.T.P. (gm./l.)	Comments
Leduc	1	1·1707	
Stahrfoss	2	1·1790	Corrected to standard *g*
Maass and Russell	3	1·1695	
Howarth and Burt	4	1·1720	Deduced from compressibility
Sameshima	5	1·1747	Probably at standard *g*
Hölemann and Hasselmann	6	1·171	

In addition, International Critical Tables give a value of 1·173 gm./l. and other authorities choose one or more of the values that have been quoted. A critical survey of the literature suggested that the true value was in the neighbourhood of 1·171 gm./l., but in view of the industrial importance of acetylene it was decided to re-determine the standard density, among other properties, by the indirect method of measuring the gas imperfection with high accuracy.

Gaseous acetylene was obtained from the National Chemical Laboratory, Teddington, the co-operation of which we are glad to acknowledge. The sample used, from the 'second batch' in the description of the preparation and purification given by Ambrose[7], was transferred to the apparatus and freed from non-condensibles.

The pressure-volume product of a sample of acetylene was accurately determined at several pressures between 230 mm. and 50 mm. of mercury and the second virial coefficient deduced from the slope of PV/P. The apparatus and the procedure were essentially as reported previously[8]. Expansion and compression values were taken in runs at 0° C., 20° C. and 40° C. The acetylene came in contact with 'Pyrex' surfaces, a tungsten reference point and considerable areas of grease-free mercury. At ordinary laboratory temperatures and in normal illumination no change suggestive of decomposition occurred: in the working apparatus the product PV of a sample of acetylene at 250 mm. pressure remained constant to better than 1 in 100,000 for periods of weeks. From the PV/P lines, after making allowance for the compressibility of the reference gas (nitrogen) and all reductions to standard conditions, the second virial coefficients can be deduced as:

Temperature (° C.)	B (cm.^{3}/mole)	
0	-191	error ± 1 cm.^{3}/mole
20	-158	
40	-133	

In the experimental range 50–230 mm. the results fit the equation

$$PV = RT + BP \text{ per mole}$$

so that the gaseous density may be expressed as $MP/(RT + BP)$ gm./l. If these relations hold up to 760 mm., then the densities of acetylene (molecular weight 26·038, $R = 0{\cdot}082054$ litre atm./deg. C. mole) at the working temperatures are:

0° C.	$1{\cdot}1716_7$	gm./l. at 1 atmosphere
20° C.	$1{\cdot}0895_9$	
40° C.	$1{\cdot}0185_6$	(error ± 0·00005)

We regard linear extrapolation from the working range to 760 mm. as perfectly acceptable. The observed PV values fit a linear pressure relation within 1–2 parts per 100,000: if there is to be significant curvature before 760 mm. is reached some portion of this would be detectable between 50 and 230 mm. Previous work[9] over the range 190–820 mm. with carbon dioxide ($T_c = 31°$ C.) showed that the PV/P relation was linear to within 2 in 100,000 over this pressure range at 22° C. No curvature was detected even with propane ($T_c = 95{\cdot}6°$ C.); which might be expected to show a greater effect. Indeed, there is no unambiguous direct experimental demonstration of a non-linear PV/P below 1 atmosphere for any monomeric substance. An alternative approach is to consider the form of the PV/P curve as obtained from accurate high-pressure data at a reduced temperature near that of acetylene in the present experiments, that is, $T/T_c = 0{\cdot}88$–$1{\cdot}02$. The isotherm of xenon at 16·65° C. ($T/T_c = 1{\cdot}00$) over the range 20–58 atmospheres was examined by Beattie, Barriault and Brierley[10], who represent their data by an equation indicating that the PV/P relation between 0 and 1 atmosphere includes a term in P^2 which amounts to a non-linearity of 3 in 240,000. For ethane at 25° C. ($T/T_c = 0{\cdot}96$) Beattie, Hadlock and Poffenberger[11] have examined the isotherm from 11 to 40 atmospheres: by fitting a power series equation to their results it has been shown that the curvature over 0–1 atmosphere is close to 2 in 100,000 on the PV value. It seems unlikely that acetylene should show a PV/P curvature markedly greater than these values.

Taking all the evidence for the validity of the extrapolation together, we have every confidence in the quoted densities. The differential compressibility method as a means of determining density has two advantages over direct determinations: (1) Comparative insensitivity to purity of material. Previous experience emphasizes the difficulty of removing the final traces of oxygen, nitrogen, hydrogen, inert gases and carbon dioxide from experimental gases and vapours. 0·1 per cent of either hydrogen or carbon dioxide, a significant amount if the density is determined directly, is immaterial in the virial method. (2) The only absolute determination is that of the pressure required for the pressure axis of the PV/P plot. For acetylene a precision of 0·1 mm. in 100 mm. suffices.

Production of High Concentrations of Hydrogen Atoms

RECENTLY we wished to produce high concentrations of hydrogen atoms in flowing gas at pressures of about 0·08 mm. of mercury. An electrodeless discharge is the most suitable source at this pressure, but although several attempts were made to use such discharges maintained by microwave radiation, a stable discharge could not be obtained at pressures less than 0·12 mm. of mercury with power inputs of up to 250 W. The discharge was therefore maintained using 9·7 Mc./s. radiation from a 350-W. radio-frequency oscillator, when the method described below proved very satisfactory. About 25 cm. downstream from the discharge, the atomic concentration was 50–60 per cent. This compares favourably with most values quoted in the literature, and using microwave radiation from a 'Raytheon' diathermy unit at 0·12 mm. mercury pressure, fewer than 10 per cent atoms were obtained. Atomic concentrations were measured with a Wrede gauge with an orifice of

0·13 mm. diameter, the differential pressure being measured directly with a sensitive differential Pirani bridge.

Discharges at this frequency spread very readily at low pressures, but this was overcome by fitting an electrostatic screen between the discharge tube and the exciting coil. The 'Pyrex' discharge tube was 12 cm. long and had an internal diameter of 3 cm. Before use, it was washed out with hydrofluoric acid and distilled water. Hydrogen entered along the axis of the tube and left at the other end through a tube joined at right angles to the discharge tube. The electrostatic screen consisted of four or five strips of copper foil 10 cm. long and ½ cm. wide laid longitudinally along the discharge tube, held at one end by asbestos string and at the other end by an earthed wire. A spiral of thin asbestos string was wound on to the tube in order to preserve a clearance of about 3 mm. between the earthed foil and the exciting coil.

The coil consisted of six turns of 8 mm. copper tubing wound so as to give a 3 mm. clearance all around the tube. A variable air-condenser was connected across the coil and adjusted to give the brightest discharge. Using damp hydrogen, the bright crimson discharge was completely contained within the discharge tube. When the earthed wire of the screen was disconnected, the discharge spread more than 1½ metres down the line.

The discharge was struck with the help of a Tesla coil, and a jet of cold air played on the tube, since this tended to collapse slightly after prolonged use. Providing no short-circuit was allowed to develop between the earthed screen and the exciting coil, this discharge tube was very satisfactory and could be used for long periods.

We wish to thank Dr. D. Roaf for suggesting the use of the screen. This work was carried out as part of Contract *AF*61(514)–1117 with the Air Research and Development Command of the United States Air Force.

Oxidation of Ferrous Ion in Aqueous Solution by Atomic Hydrogen

IT is well known that hydrogen atoms are able to act as oxidizing agents by virtue of the high energy of formation (~ 104 kcal./mole) of the H—H bond. Thus they dehydrogenate many organic substances where C—H bond energy is only of the order of 80–90 kcal./mole.

Experimental results were obtained in aqueous solutions containing, for example, ferrous ions which were irradiated with *X*- or γ-rays[1,2] or with ultraviolet light[3,4] which led to the assumption that hydrogen atoms are formed in these systems. These atoms would then oxidize the ferrous ion to ferric. In several experiments the reaction was found to be dependent on *p*H, and Weiss[5] postulated the formation of the $H_2{}^+{}_{aq}$ ion to account for this dependence. Coulson[6] considered the stability of $H_2{}^+{}_{aq}$. Schematically the reaction may be written[3]:

$$Fe^{2+}_{aq} + (H + H^+{}_{aq}) \rightarrow Fe^{3+}_{aq} + H_2$$

To test this hypothesis we used hydrogen atoms produced by an electrodeless discharge operated at 27 Mc./s. and 0·7 kW. in hydrogen alone at 20 mm. mercury, and also in helium – hydrogen mixtures at total pressures of up to 50 mm. The hydrogen atoms thus produced were passed into the aqueous solution containing ferrous ions. Suitable blank experiments were carried out and the reducing action of the hydrogen atoms produced was measured quantitatively by reaction with silver nitrate solutions. The reduction of ferric ions in the same apparatus was also studied.

To investigate the oxidation of ferrous ions, solutions containing always 0·01 *N* ferrous sulphate and varying concentrations of sulphuric acid were treated with hydrogen atoms under constant conditions of hydrogen-pressure, discharge, rate of gas flow and duration of experiment. Qualitatively the oxidation of ferrous ion was observed and followed to 10 per cent conversion by measuring the optical density at 305 mμ. At other acid concentrations account was taken of the change in the molar extinction coefficient with simultaneous changes in *p*H and sulphate concentration. Using a lower percentage of conversion, to avoid competition with reduction of ferric ions by hydrogen atoms, the following quantitative results were obtained: with 0·7 *N* sulphuric acid, ΔFe^{3+} (m.moles/l.) = 0·54 ± 0·09. This yield remains constant to approximately *p*H 3; thus with 0·001 *N* sulphuric acid (*p*H 2·95) ΔFe^{3+} = 0·50. With 0·0005 *N* sulphuric acid (*p*H 3·30), ΔFe^{3+} = 0·31 ± 0·07 was obtained under identical conditions, indicating that if the reaction depends on *p*H, this dependence manifests itself at or above *p*H 3 only where the ferrous–ferric system becomes unstable through hydrolysis. This supports the results of Allen[2] and is not in disagreement with the photochemical evidence of Lefort[4].

Our results show that hydrogen atoms, produced outside the aqueous system and introduced into it as such, are capable of oxidizing ferrous ions. The oxidation step may depend on *p*H. If so the reason for this may be in the mechanism involving $H_2{}^+$ ions as proposed by Weiss. Alternatively, the reaction may proceed through hydrogen abstraction from the hydration shell of the ferrous ion[7].

Structure of Pyruvate in Aqueous Solution

IN a recent publication and its addendum by Dickens and Williamson and by Bellamy and Williams[1], it was reported that the infra-red spectra of lithium pyruvate and hydroxypyruvate in the solid state show no ketonic carbonyl peak, and it was suggested that these compounds exist as the hydrate, $RCH_2C(OH)_2COO^-Li^+$, in the solid and in aqueous solution and that this hydrate may be the substrate for the enzymatic reduction of pyruvate to lactate at neutral *p*H.

In contrast to solid lithium pyruvate, a solution of sodium pyruvate in heavy water shows a strong infra-red carbonyl absorption at 1,710 cm.$^{-1}$ (Fig. 1). A C—H bending peak at 1,358 cm.$^{-1}$, typical of a methyl ketone, as well as the strong carboxylate absorption at 1,610 and 1,410 cm.$^{-1}$, are also evident. Similar carbonyl peaks were found in deuterium oxide solutions of pyruvic acid (1,725 cm.$^{-1}$), α-ketoglutaric acid (1,722 cm.$^{-1}$) and sodium α-ketoglutarate (1,710 cm.$^{-1}$) and for sodium pyruvate in a potassium bromide pellet (1,715 cm.$^{-1}$). Furthermore, the ultraviolet absorption maximum of aqueous pyruvate[2] at 330 mμ is similar to that of α-ketoglutarate[3], oxalacetate[3], pyruvic acid[4] and ethyl pyruvate[4], and has the location and intensity expected for a carbonyl group in the alpha position to an unsaturated group[5].

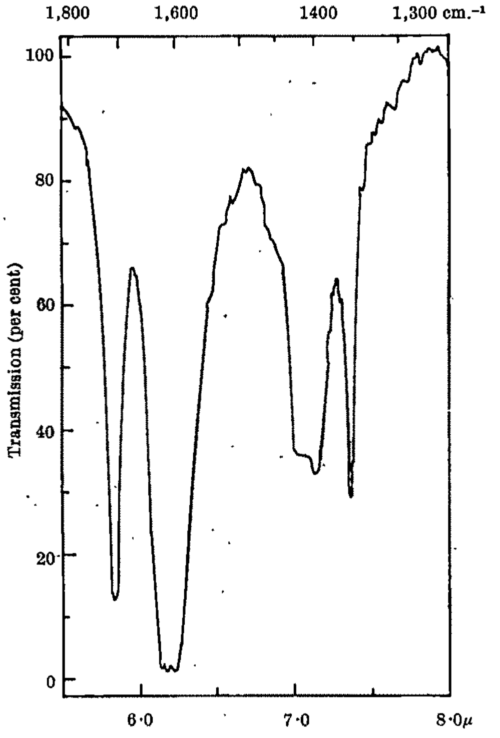

Fig. 1. Infra-red spectrum of 0·5 *M* sodium pyruvate in deuterium oxide; 0·05 mm. path-length; calcium fluoride cells; Perkin-Elmer model 21 double-beam spectrophotometer

It is concluded that pyruvate as well as pyruvic acid exist in the carbonyl form in aqueous solution, which is in accord with the low electron withdrawing ability of the negatively charged carboxylate group compared to a carboxylic acid group[6] (cf. also ref. 1) and is consistent with the chemically attractive mechanism postulated for the enzymatic reduction of pyruvate by transfer of a hydride ion from reduced diphosphopyridine nucleotide to the partially polarized, unsaturated carbonyl group[7]. The existence of solid lithium pyruvate in the hydrated form may be due to increased electron withdrawal by the concentrated positive charge of the lithium cation, or to hydration of the lithium ion by the hydroxyl groups of hydrated pyruvate in the crystal lattice, which would be favoured by the exceptionally large energy of hydration of the lithium ion.

We are grateful to the National Science Foundation and the National Institutes of Health (Grant *C*-3975) for financial support.

Faraday Fading of Earth Satellite Signals

THE rate of fading of Earth satellite signals caused by the ionospheric Faraday effect was used by British workers[1, 2] to make estimates of the integrated electron content of the ionosphere up to the height of the satellite. The values obtained were, however, apparently too high. A possible reason for this is failure to take into account the radial velocity component of the satellite which, for certain portions of the orbit, can cause an appreciable contribution to the fading.

The complete expression for the rate of fading due to the Faraday effect is:

$$\frac{d\varphi}{dt} = 2{\cdot}36 \times 10^4 . f^{-2} . B \left\{ \frac{\partial}{\partial t} (\cos\theta \sec\delta) \int_{h_0}^{h_s} N(h) dh + (\cos\theta \sec\delta) \frac{dh_s}{dt} . N(h_s) \right\} \text{radians sec.}^{-1}$$

where f is the transmitted frequency in c./s., B the Earth's magnetic field in gauss, θ the angle between the direction of propagation and the magnetic field, δ the zenith angle, and $N(h)$ the electron density per cm.^{3}. This expression arises from the fact that h_s, the upper limit of the integral (the height of the satellite), is a function of time. The rate of fading therefore consists of two terms, one of which depends upon the integrated electron content up to the height of the satellite, and the other upon the electron density at the satellite. The second term of the equation vanishes only at perigee and apogee or for a circular orbit (and, of course, when $N(h_s)$ is zero). For the general case, however, the two terms cannot be evaluated independently from observed rates of fading. A value of $\int N dh$ computed on the assumption that the rate of fading depends only upon the first term would be too high. For the two orbits used for the estimates of $\int N dh$ referred to, the contribution of the second term apparently cannot be neglected.

A detailed discussion of these considerations will be published elsewhere.

Neutron Activation Analysis using an Internal Standard

To correct for differences in neutron flux and neutron shadowing between sample and reference a method has been developed which uses an internal standard.

Instead of irradiating a known amount of the element as a reference, two quantities a and b of the sample are irradiated, an amount c of the element X to be determined being mixed homogeneously with b.

The material subjected to analysis should contain at least one element Y, which gives rise to an isotope measurable with good accuracy and having a half-life long in comparison with the isotope of the species analysed.

When both samples are measured at a time t, after the complete decay of the species due to X, the ratio of the activities due to Y will be given by

$$\frac{A_{t(Y)}}{A'_{t(Y)}} = \frac{a}{b} \cdot \alpha \qquad (1)$$

α being a correction factor which compensates for any difference in the neutron flux received by the two samples and/or for a different neutron shadowing.

By analysis of the decay curves, the activities $A_{\tau(X)}$ and $A'_{\tau(X)}$, due to the element X, can be computed at the end of the irradiation time τ.

The specific activity of the sample, due to X, will be given by:

$$S_{\tau(X)} = \frac{1}{c}\left[A'_{\tau(X)}\,\alpha - \frac{b}{a}\,A_{\tau(X)}\right] \qquad (2)$$

and the percentage of X present by:

$$\% X = \frac{A_{\tau(X)} \times 100}{a \times S_{\tau(X)}} \qquad (3)$$

It is also apparent that simultaneous irradiation of both samples is not required.

The method is of general use but is likely to be more important in the case of neutron sources of low intensity. In this case neutron-shadowing will be greater, as it is necessary to take large samples to reach a sufficiently high activity of the analysed element. Even when using the *BR-I* reactor, however, operating at $10^{11}n$/cm.^{2} sec., neutron shadowing was observed, causing the specific activity to be low by 15 per cent when irradiating 1-gm. samples of high-alloy cobalt steel.

The method was successfully applied in the determination of vanadium and tungsten in high-alloy steels and will be described in detail elsewhere.

Error at a Rectangular Corner in Relaxation Methods

In "Relaxation Methods in Theoretical Physics" (R. V. Southwell, Clarendon Press, 1946, p. 133) results obtained by R. W. G. Gandy, using the method of relaxation, are given for the capacity C, per unit length, of a cylindrical condenser, the cross-section of which consists of concentric squares having sides in the ratio $2\sqrt{2} : 1$. Three cases are illustrated (Fig. 54): (a) the two squares are diamondwise to each other; (c) the sides are parallel; (b) an intermediate position.

It is with cases (a) and (c) that we are here concerned. We have calculated the value of C in these two cases from the analytical solution given by F. Bowman[1], using Milne-Thomson's "Table of Elliptic Functions".

In case (a) we obtain the value 6·630 for $4\pi C$, and in case (c) the value 6·596, as compared with Gandy's result of 6·715 in both cases.

H. Jeffreys and B. S. Jeffreys[2] give, for case (c) with sides in the ratio 2 : 1, results obtained analytically and by relaxation. For this ratio of sides we have computed $4\pi C$ for case (a) and obtain 10·660, but no corresponding result obtained by relaxation appears to be available.

These results may be of interest to those using relaxation methods, as giving some idea of the amount of error that may be expected at a rectangular corner.

Two- and Three-Dimensional Flow of Grains through Apertures

In the course of experiments on the physics of the granular mass, the rate of discharge of three size grades of a dry, sharp sand was measured (a) from wide cylindrical vessels through circular and elliptical orifices, (b) from wide rectangular vessels through long slits. In both cases the apertures were situated on the central axis of a horizontal base. The mean particle sizes P of the size grades (18 × 36, 36 × 60, 44 × 120 British Standard mesh) were 0·053, 0·037, 0·020 cm. From the measured rate of discharge Q gm./sec., a mean linear velocity v cm./sec. was calculated as:

$$v = Q/\rho A \qquad (1)$$

A cm.^{2} being the area of the aperture and ρ the particle density in gm./cm.^{3}. To find the true linear velocity of the particles from v it would be necessary to measure the bulk density of the flowing material at the orifice; this has not been done.

The data for the three-dimensional flow systems of experiment (a) were found to be well correlated in a plot of the dimensionless magnitudes,

$$\varphi = \frac{v}{\sqrt{gH}} \text{ and } \left(\frac{P}{H}\right) \qquad (2)$$

where g cm./sec.^{2} is acceleration due to gravity and H is the perimetral diameter of the aperture, defined as 4 (area)/perimeter. The elliptical apertures had equal areas of 0·32 cm.^{2} and eccentricity increasing from zero to 0·995: the velocity v decreased with increasing eccentricity. Representation (2) was adequate for accounting for aperture shape. As earlier workers have shown, this representation has the advantage that φ, which depends essentially on the aperture and not the particles, does not vary much with H, Q being nearly proportional to $H^{2\cdot5}$ for flow through circular apertures. Fowler and

Glastonbury[1] have also used the perimetral diameter for correlation of flow through apertures differing in shape.

The two-dimensional flow system of experiment (*b*) gave results which, under representation (2) (with H equal to twice the slit-width), fell on a curve distinct from that found in experiment (*a*). It can be shown that the results of experiments (*a*) and (*b*) can be reconciled by reference to the size of aperture that is just blocked by the particles.

A chain of particles having an average of about 2·7 members obstructs a slit, and a chain having about 4·3 members obstructs a circular orifice[2]. It is not unreasonable to suppose that the rate of discharge depends on the number N of chains that span an aperture, being zero for N unity. The results from experiments (*a*) and (*b*) were therefore plotted in terms of the dimensionless magnitudes,

$$\psi = \frac{v}{\sqrt{gP}} \text{ and } N \qquad (3)$$

where (in order to include the elliptical apertures)

$$N = \frac{H}{K}, \quad \begin{matrix} (K \simeq 4{\cdot}3\,P \text{ for three-dimensional flow}) \\ (K \simeq 5{\cdot}4\,P \text{ for two-dimensional flow}) \end{matrix} \qquad (4)$$

and K is the perimetral diameter of the aperture that is just blocked. The ratio of kinetic energy of a particle to the potential energy lost in falling through a particle diameter is $\frac{1}{2}\psi^2$, which is therefore a particle characteristic.

It is clear from Fig. 1 that representation (3) satisfactorily correlates the two- and three-dimensional flow systems.

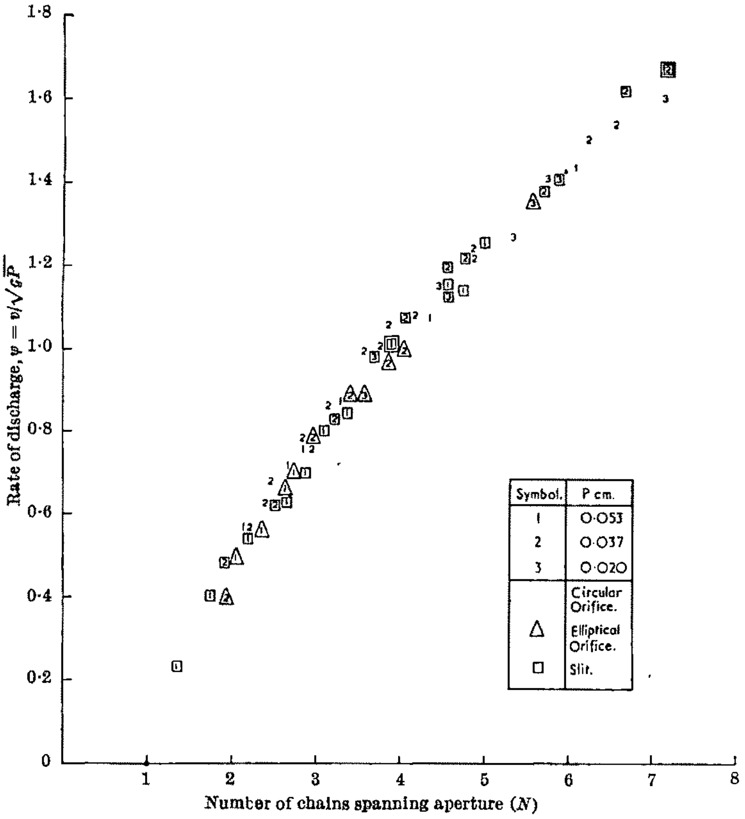

Fig. 1. Two- and three-dimensional flow of grains through apertures differing in shape and size

Further details and results for other materials and for flow from narrow vessels are given in a paper to be published elsewhere.

Observations of the Pacific Equatorial Undercurrent

We have succeeded in measuring the flow of the Pacific Equatorial Undercurrent first described by Cromwell, Montgomery and Stroup[1]. Taut-wire buoys[2] were anchored in 2,300 fathoms as reference points. Measurements at different depths were made by suspending a modified Roberts current meter[3] from a drifting ship. A vibrotron pressure element was used to give the depth of the meter, and the drift of the ship relative to the anchored buoy was measured by radar. To define the bottom of the undercurrent four measurements were made with Swallow type neutral buoyant floats[4]. These measurements were the principal object of the Dolphin Expedition March 27–June 10, 1958, one of the special cruises of the International Geophysical Year oceanographic programme.

Five buoys were laid on long. 140° W. at latitudes 2° N., 1° N., 0°, 1° S. and 2° S. Measurements were made from two ships, *Horizon* of the Scripps Institution of Oceanography, University of California, and *Hugh M. Smith* of the Pacific Oceanic Fisheries Investigation, U.S. Fish and Wildlife Service. The equator station was monitored by one ship during April 6–28. The second ship made measurements at the other four buoys in rotation.

On the second half the expedition *Horizon* made measurements with the Roberts meter at 180-mile intervals along the equator from long. 137° W. to 89° W. For these measurements the reference buoy was a free-floating parachute drogue[5] with the parachute suspended at 1,000 m. Parachutes at this depth were occasionally used for reference at long. 140° W. and their motion with respect to the anchored buoys was about 0·2 knots.

The Undercurrent is an east-flowing current centred at the equator just below the west-flowing South Equatorial Current. Measurements at long. 140° W. indicate a transport of the order of 30 million cubic metres a second or about the same as the transport of the Florida Current. Measurements along the current indicate that it is at least 3,500 miles long.

At long. 140° W. the Undercurrent is symmetrical about the equator. During the 22-day observational period the highest velocities toward the east were always recorded at the equator and at a depth of 100 ± 13 m. The velocities in this core were between two and three and a half knots. During this period the South Equatorial Current was flowing westward at speeds between half a knot and one and a half knots.

The top and bottom of the Undercurrent are at about 30 and 300 m. respectively for 0°, 140° W. The Swallow drogues indicate a small flow to the west between 500 and 700 m.

The Undercurrent becomes thinner and weaker on either side of the equator. At 2° N. and S. the average thickness was 30 m. and the average maximum velocity was 0·6 knots.

Measurements made along the equator showed no diminution in the core velocity between long. 140° and 95° W. At 92° W. (25 miles west of San Isabela Island in the Galapagos) the core velocity was 1·2 knots. At 89° W. (east of the Galapagos) the Undercurrent was missing. The depth of the core rose from 100 m. at 140° W. to 52 m. at 98° W., a slope of $1 \cdot 3 \times 10^{-5}$. Stations of 95° and 92° W. showed the core dipping down. It was at 92 m. at 92° W.

Three days after the completion of these measurements, Townsend Cromwell, who discovered the Pacific Equatorial Undercurrent in 1952 and gave it its present name, was killed in an aeroplane crash near Guadalajara, Mexico, on June 2, 1958, on his way to join another Scripps Institution oceanographic expedition at Acapulco. We would like to suggest that this current be called the Cromwell Current.

Protein Synthesis as a Basis for Chloramphenicol-Resistance in *Staphylococcus aureus*

It has been established that chloramphenicol is a specific inhibitor of inducible enzyme formation and of protein synthesis in general[1]. The antibiotic does not exert its effect on protein synthesis by inhibition of amino-acid activation, by inhibition of peptide bond formation, or by inhibition of incorporation of amino-acids into cell-wall[2]. Pardee, Paigen and Prestidge[3] reported that ribonucleic acid synthesized in the presence of chloramphenicol possessed an electrophoretic mobility which differed from that of normal ribonucleic acid synthesized in the absence of the antibiotic. It was later found by Neidhardt and Gros[4] that this altered ribonucleic acid was unstable and was rapidly degraded in the absence of chloramphenicol. These observations have prompted the suggestion by Gale[5] that "chloramphenicol alters, or in some way interferes with the function of the ribonucleic acid component concerned in amino-acid incorporation".

Two mechanisms of resistance to chloramphenicol have previously been observed. The enzyme 'chloramphenicol reductase' has been related to resistance of *Escherichia coli*[6] and a decreased permeability to chloramphenicol was noted by Kushner[7] in a strain of *Pseudomonas aeruginosa* which was resistant to the antibiotic.

Evidence has recently been obtained in this laboratory which indicates that a third mechanism of resistance is operative in *Staphylococcus aureus*. It has been found that both whole cells and cell-free preparations of a resistant strain are capable of forming inducible enzymes in the presence of a concentration of chloramphenicol which causes complete inhibition of the formation of enzyme in a sensitive strain.

Two strains of *Staph. aureus*, which have been described previously[8], were used throughout the study. The sensitive organism (strain *S*) was inhibited by 5 μgm. chloramphenicol per ml. and the resistant organism was capable of growing in the presence of 500 μgm. chloramphenicol per ml. The effect of chloramphenicol on formation of the two inducible enzymes, nitrate reductase and β-galactosidase, has been determined using procedures for induction and assay of the two enzymes which have been described previously[9]. The methods of Gale and Folkes[10] were used in experiments involving cells irradiated with ultrasonic waves.

The effect of chloramphenicol on induction of both enzymes in whole cells of strains *S* and *R* is shown in Table 1. In this experiment, the effect of adding 10 μgm. chloramphenicol per ml. to the system at zero time and at 2 and 4 hr. after the start of induction is compared. Addition of chloramphenicol at zero time results in a marked inhibition of the formation of enzyme in strain *S*; at 6 hr. the amount of β-galactosidase is only 12 per cent of that formed in the absence of the antibiotic. A similar inhibition is noted in the case of nitrate reductase. With strain *R*, however, addition of 10 μgm. chloramphenicol per ml. at zero time has no effect on the formation of enzyme. Another noteworthy effect is that obtained when chloramphenicol is added to the system after induction has proceeded for 2–4 hr. It is seen that this procedure results in an immediate cessation of

* μMoles nitrite produced per mgm. sonicate per 30 min.

the formation of enzyme by strain *S*, which persists throughout the course of the experiment. On the other hand, addition of 10 μgm. chloramphenicol per ml. to strain *R* after synthesis has started does not result in inhibition.

In order to determine whether the results obtained with whole cells were due to a resistant protein-synthesis mechanism or to decreased permeability of strain *R* to chloramphenicol, an inhibition experiment was performed using cells which had been subjected to ultrasonic disintegration in a 10-kc./s. 'Raytheon' oscillator. The viable count of the suspension after sonication was 3×10^6 cells per ml. compared with 9×10^9 cells per ml. before sonication. These disrupted suspensions were fully capable of forming enzyme. It may be seen (Table 2) that, here again, strain *R* is capable of forming enzyme in the presence of a concentration of chloramphenicol which completely inhibits the formation of enzyme in strain *S*. From these results it is concluded that permeability is not the main source of resistance in this organism, but rather that some alteration has occurred in strain *R* which makes protein synthesis less susceptible to the inhibitory effect of the antibiotic. Although the nature of the altered mechanism of synthesis has not been determined, certain experiments have been performed which give some insight into the nature of the resistance. First, it has been found that growing strain *R* in the presence of chloramphenicol or pre-incubating cells in the presence of the antibiotic prior to induction does not increase subsequent resistance to it in terms of protein synthesis. It would appear, therefore, that resistance is a stable characteristic of the cells and does not depend upon the presence of the antibiotic. It has also been found that cells which have been pre-incubated in the induction medium in the presence of chloramphenicol and inducers (nitrate and galactose), and then washed and resuspended in induction medium plus inducers, do not form enzyme at a faster rate than cells which have not been pre-incubated. This would indicate that chloramphenicol exerts its inhibitory effect by interfering with normal ribonucleic acid function as suggested by Gale[5], and the ribonucleic acid formed in the presence of chloramphenicol is not available for subsequent protein formation. These results would also support those of Ben-Ishai[11], who found that preformed ribonucleic acid did not function in subsequent protein synthesis.

Two features of the results obtained should be mentioned. First, with both strains *S* and *R*, sonicated cells are more susceptible to chloramphenicol than whole cells, indicating that a permeability barrier of sorts does exist. However, this barrier is no more pronounced in strain *R* than in strain *S*, since the quantitative difference in the concentration of chloramphenicol required for inhibition of the formation of enzyme in whole cells and in sonicates is no greater in strain *R* than in strain *S*. Secondly, the concentration of chloramphenicol required to inhibit formation of enzyme is much less than that required for inhibition of growth. This dichotomy is probably due to the difference in time intervals used in induction experiments and in growth experiments. For example, in the experiments shown here six hours was the maximum time of observation. In growth experiments, particularly those involving high concentrations of chloramphenicol, the maximum time interval is often in the range of 150–200 hr. It is probable that the concentrations of chloramphenicol required to inhibit enzyme synthesis would approach that required for inhibition of growth if induction experiments could be carried out for several days. For this reason, a direct correlation between resistance in terms of growth and resistance in terms of protein synthesis, must await experiments using continuous cultivation of cells in a chemostat.

Permeabilizing Effects of Heparin and Heparin-like Substances

At a concentration of 0·001 per cent (w/v), heparin provokes liberation of the clearing factor from isolated perfused rabbit heart[1]. Desulphurated α-heparin and β-heparin have a similar activity, but chondroitinsulphuric acid and hyaluronic acids do not, in spite of their great chemical similarity to the three active substances[2]. Furthermore[3–5], heparin at 0·4 gm. per cent (w/v) induces an obvious diastolizing effect on a Straub preparation of isolated frog heart. Such cardiac diastolization can also be obtained by desulphurated heparin and by β-heparin at the same concentration, but not by chondroitinsulphuric acid or hyaluronic acid; only the action of β-heparin is irreversible. Diastolization is completely abolished if an over-dosage of 12 mgm. per cent of calcium ions is added to the Ringer solution.

These effects can be tentatively interpreted as an increase of permeability, at the level of cell membranes, perhaps due to removal of calcium.

In order to confirm such a hypothesis experiments have been performed on the outflow of rubidium-86 from the isolated diaphragm of albino rats.

Preliminary observations by Marro in collaboration with Hashish, made in the Zoophysiological Laboratory of Copenhagen under the direction of Prof. Ussing, seem to show a change in the outflow curve of the labelled ion, even at very low concentrations of heparin ('Eparina Novo' in ampoules).

Other experiments carried out with the same method[6] [7] in our laboratories, but with 'Boots' heparin (sodium heparin 110·9 T.U./mgm.), showed the same effect, only at higher concentrations.

The samples of liquids were tested for radioactivity using a Geiger counter for liquids (type *M* 6, 20th Century Electronics).

Three groups of experiments were performed at 38° C., each on five muscles: a control group; a second group in which 70 min. after washing had started the Krebs solution was replaced by another containing heparin at a concentration of 0·05 per cent (w/v); and a third group in which, always after the same lapse of time, Krebs solution was replaced by another in which the calcium ion concentration was reduced to two-thirds of that in normal Krebs solution.

Fig. 1 shows the average results obtained from the three experimental groups, in the same order as above mentioned, from left to right; the relative counts/min. are shown on a logarithmic scale. Both the addition of heparin and the reduction of calcium ion concentration seem to modify the kinetics of exchange of rubidium-86, increasing its outflow; the modification induced by heparin appears to be quantitatively greater than that following partial removal of calcium ions.

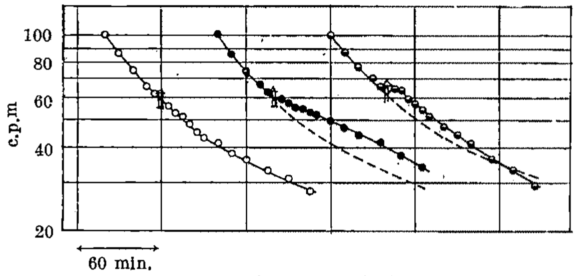

Fig. 1. For key see text.

Therefore, it seems reasonable to conclude that in rubidium exchange heparin exerts a permeabilizing action; this effect may perhaps be related to a removal of calcium ions, since it can be, at least partially, reproduced by a decrease in calcium content of the perfusing solution.

Isolation from Human Blood of a New Substance associated with Fat Transport Activity

Fat absorption was studied on a number of patients with various neoplasms. In all cases, after ingestion of iodine-131-labelled triolein dissolved in olive oil, the excretion of the labelled fat and its metabolites was followed by scintillation counting. The rate of absorption into the blood stream, and the state and distribution of the absorbed substances were investigated as follows.

The activity of aliquots of blood was measured at appropriate intervals after the injestion, and relatively larger aliquots (20 ml.) were drawn for chemical examination near the peaks of activity (2 and 4 hr.) and also after 6 hr.; at this time there was a more or less pronounced decrease in the amounts of labelled compounds in the blood. The proteins in the pooled blood (60 ml.) were precipitated with a mixture of methylal and methanol (4 : 1 to 15 vol. blood); this protein precipitant[1] [2] was used in preference to the usual trichloracetic acid because it affords milder conditions of treatment (neutral reaction at room temperature).

The methylal–methanol extract contained 75–85 per cent of the whole blood activity. This includes 7–10 per cent of activity present as inorganic iodide. After evaporation to dryness *in vacuo* in the absence of oxygen, the residue was extracted with petroleum ether (60–80°), and this extract contained practically the whole activity in about 200 mgm. of fatty material. The inorganic iodide was either removed from the extract ('De-acidite F F'; Cl-form) before chromatography, or the solution was submitted without 'De-acidite' treatment to adsorption chromatography on a silica–petroleum ether column (20 mm. × 600 mm.; 80 gm. silica). The adsorbed substance was developed by gradient elution with petroleum ether – ether – methanol; the shapes of the eluent and mixing chambers were chosen in such a way as to give a linear gradient with an angle of about 40°; the start of the gradient was delayed by developing with the pure, less polar solvent until 5 × 10 ml. fractions have passed through the column.

There were two very pronounced and sharp peaks of activity in the eluted fractions: first in order of emergence, a smaller one containing about 10 per cent of the activity of the original solution, and then a second peak containing about 60 per cent of the total activity adsorbed on to the column.

The material forming the first peak has as yet not been extensively investigated; it contains, however, fatty acids and cholesterol, and is probably largely a cholesterol oleate.

The substance contained in the second peak appears to be homogeneous. After hydrolysis it contains free fatty acids, phosphate, choline, and eight to nine amino-acids: alanine, arginine, cysteine, glutamic acid, glycine, leucine, serine, threonine, and valine. However, although the one-dimensional paper chromatograms were run with markers, the results so far obtained are of a preliminary character, and work on the identification and quantitative estimation of these amino-acids is proceeding.

Solutions of the unhydrolysed substance do not contain detectable amounts of inorganic phosphate, free amino-acids, fatty acids or choline. On paper electrophoresis at *p*H 5·0 and at 8·6 the substance remains homogeneous on the origin, and no moving components could be detected on the paper in either direction of the current. On paper chromatography in several solvent systems the substance moves as a homogeneous spot.

Quantitative determinations of choline[3], phosphorus[4], and amino-acid nitrogen[5] point to the relation 1 : 3 : nono- or deca-peptide. The substance is probably a phosphorylated pepto-lecithine-like compound; we have no indication yet where the two additional phosphoric acid residues might be.

In four of the cases examined, this substance contained the greatest amount of activity (about 60 per cent. However, in the case of one patient, this substance though present in the usual quantity, contained very little activity. In this case 59·6 per cent of the activity was contained in another fraction, which on analysis proved to contain a similar peptide, fatty acids and phosphorus but no choline. The reason for this is not clear and work is continuing in this direction.

It is interesting to speculate about the possible relation of this pepto-lecithine-like substance with the peptide of the lipid mobilizing factor described in the literature[6]. In fact, the two-dimensional amino-acid chromatograms of the hydrolysates of our substance show great similarity to those of the fat mobilizing factor found in human urine[7] (Dr. Ivor Smith, private communication).

We wish to thank Sir Charles Dodds and Prof. J. E. Roberts for their interest and support. Our thanks are also due to Mr. C. F. M. Rose and our medical officer, Dr. K. M. Jones, for their invaluable help.

Movements of Potassium in Rabbit Auricles

Movements of potassium-42 have been measured in beating right and quiescent left rabbit auricles at 37° C., immersed in modified Krebs saline containing 5·2 mM potassium, and gassed with an oxygen/carbon dioxide mixture to a pH of 7·35 [1]. Efflux was measured by counting the tissue directly in a bath of 10 ml. capacity, through which flowed inactive medium, after a period of immersion in active medium[1,2]. Influx measurements were made in the same apparatus in the presence of active medium. Although the contribution of the medium to the observed counting rate was high throughout, and the total increase in count was never more than twofold, reproducible increments in tissue count were obtained for about 120 min. Retropolation to zero time of the counts between 5 and 24 min. of efflux, plotted semi-logarithmically, allowed the true bath background to be obtained, free from the effects of displacement of medium and absorption of counts by the tissue. In the absence of tissue, more than 99·5 per cent of the active medium was washed out of the bath within 3 min., on changing to inactive medium. The method of measuring influx offered the advantage that influx and efflux could be followed in the same tissue, and that the tissue could be stimulated during the course of influx measurement.

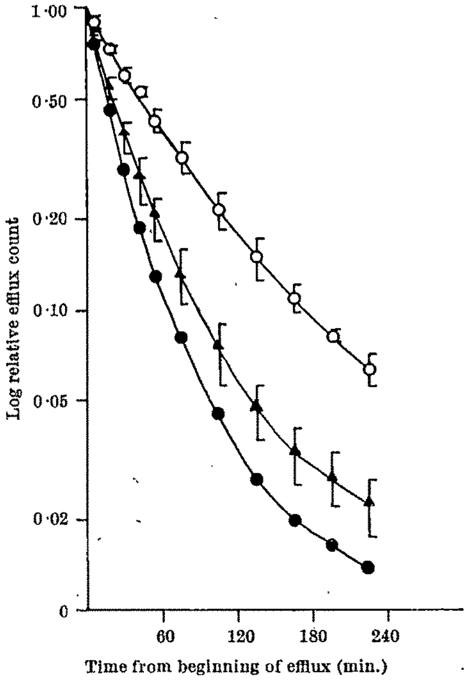

Fig. 1. Efflux of potassium-42 from rabbit auricles; ○, efflux from non-beating left auricles; ▲, efflux from right auricles beating at 170–210/min.; ●, efflux from left auricle stimulated electrically at 210/min. Range marks, standard error of three right and two left auricles. The curve of non-beating left auricles is significantly different from those of beating right auricles ($P < 0·01$), and stimulated left auricle ($P < 0·05$)

Neither influx nor efflux of tracer followed a strictly exponential course. The initial influx rate-constant, k_i, was always smaller than the initial efflux rate-constant, k_e, measured after 40 min. of influx. Both values, especially in right auricles, decreased with time. The ratio of initial k_i to k_e was significantly smaller ($P < 0·01$) in right ($0·723 \pm 0·042$; standard error of 6 determinations), than left auricles ($0·892 \pm 0·026$; standard error of 6 determinations). Losses of potassium, which were slight (about 2 per cent/hr.), and equal for right and left auricles, do not provide a satisfactory explanation for these differences. However, the results may be due to an inhomogeneity of the auricle potassium, which is greater in right than left auricles[1]. When a left auricle was stimulated electrically to beat at the same rate as spontaneously beating right auricles (about 200 per min.), its curves of efflux (Fig. 1) and influx closely resembled those of right auricles. The difference in the shape of curves of right and left auricles appears to depend, therefore, on the activity of the tissue, and results from incomplete equilibration of the potassium which is exchanged at each beat with the rest of the cell potassium, rather than on the presence in the right auricle of special cells which exchange their potassium more rapidly. This is supported by the observation that right auricles, after treatment with some drugs in concentrations which just inhibited mechanical activity (for example, 8×10^{-6} M quinidine), had influx and efflux curves, and a ratio of initial k_i to k_e

(0·912 ± 0·018; 4 determinations), which were like those of left auricles. It follows that computation of potassium fluxes, especially in right auricles or beating auricle pairs[1,3], using the model based on single exponential exchange[2], will give results which are misleading.

Cocaine, quinidine and atropine decreased the inward and outward movements of potassium-42 both in beating right and quiescent left auricles. These drugs, acting on initially beating right auricles, had log molar dose-response curves which were rectilinear and parallel; cocaine was approximately equal in potency to quinidine, and atropine had about one-eighth of this potency. These results are consistent with the hypothesis that the drugs decrease the permeability of the cell membrane to potassium ions[4].

I am indebted to Prof. M. Weatherall for his advice and guidance in this work.

Substances depressing the Phagocytic Activity of the Reticulo-Endothelial System

In previous publications[1-3] we have reported the effect of various steroids, stilbenes and aliphatic hydrocarbons on the phagocytic activity of the reticulo-endothelial system, intimating that the strongest stimulants possessed high œstrogenicity. The present communication records the relative effect on phagocytic activity of the substances which we have found to depress the reticulo-endothelial macrophages.

The experiments were carried out on 125 male white mice (*T.O.* Swiss strain) of 20–30 gm. body-weight. Five of the animals were used to assess the effect of each substance on the phagocytic activity of the reticulo-endothelial system, each animal receiving one subcutaneous injection of 0·5 mgm. of each substance daily for six days. The phagocytic activity was then measured on the eighth day by the rate of disappearance of a known amount of carbon from the circulating blood[4], the procedure being as described in a recent communication[2]. The total body phagocytic activity or phagocytic index is denoted as previously by the symbol *K*.

The results are shown in Table 1. The substances in Group 1 were administered subcutaneously in aqueous solution. For this group 25 animals were used as controls. They were given carbon only and showed an average phagocytic index or *K*-value of 26.

The substances in Group II were each given in 0·05 ml. of arachis oil. For this group 25 animals were used as controls. Each received one subcutaneous injection of 0·05 ml. arachis oil daily for six days, then carbon on the eighth day. These animals showed an average phagocytic index or *K*-value of 13.

Compared with the control values, the results show that cortisone acetate, prednisone, prednisolone and 4-hydroxytetraphenylmethane are strong depressants of phagocytic activity, whereas the other substances shown in Table 1 are mildly depressant. None o the substances used possesses high œstrogenic activity

Table 1. Substances which depress the Phagocytic Activit of the Reticulo-Endothelial System

	Substance administered	Phagocytic index (*K* value)
Group I Administered in aqueous solution, subcutaneously	Cortisone	7
	Prednisone	8
	Prednisolone	8
Control values for 25 untreated animals		26
Group II Administered in arachis oil, subcutaneously	4-Hydroxytetraphenylmethane	8
	Sitosterol	10
	Androstalone	10
	Deoxycortone acetate	10
	Ergosterol	10
	1-*p*-Hydroxyphenyl-1 : 1-diphenyl propane	10
	Lanosterol	11
	Cholesterol	11
	Stilbene	11
	4 : 4′-Dihydroxydibenzyl	11
	4 : 4′-Dihydroxystilbene	11
	3-(*p*-Hydroxyphenyl)-3-phenyl-*n*-pentane	11
Control values for 25 animals which received 0·05 ml. arachis oil subcutaneously once daily for 6 days		13

We are indebted to Sir Charles Dodds for generously supplying the majority of these substances.

Stomoxys sp. on Cattle in Uganda

It is common practice in Uganda to house cattl during the hottest part of the day, between 11 a.m and 3 p.m. (approximately 10 a.m. to 2 p.m. sun time) primarily to protect them from irritation caused b the biting fly *Stomoxys* sp. Although no factua evidence is available, it is generally assumed tha where cattle are left out continuously much of th observed loss of condition can be ascribed to thi annoyance. Were this housing unnecessary it migh be possible to avoid, not only the added expense, bu also the inconvenience caused by extra herding o extensive ranching systems.

The predominant species at the Cotton Researc Station, Namulonge, is *S. nigra* Macq. and, fro numbers of adults recorded on tethered bait cattle a diurnal cycle of activity is apparent (see Table 1) with minimum activity occurring between 11 a.m. and 2 p.m.

Regression analyses on the number of feeding adult flies on observed climatic factors indicate that saturation deficit accounts for the greatest part of the total variation of *Stomoxys* populations ($R^2 =$

Table 1. Mean Number of *Stomoxys* recorded on Two Bait Co on 15 Occasions between 17.3.58 and 5.5.58

Local time	a.m. 7	8	9	10	11	12	p.m. 1	2	3	4	5	6
No. *Stomoxys*	12·1	19·5	18·9	16·7	14·5	13·1	14·4	15·3	18·7	19·2	17·2	18

−0·435). Successive generations follow a 20–30-day interval with increased emergence preceding periods of abundant rainfall during the larval period. This confirms other work on optimum breeding conditions[1].

Adult *Stomoxys* are readily caught in modified tsetse fly traps[2] when placed up to 10 yards from cattle. The efficiency of these traps decreases as the distance increases so that at 30 yards very few flies are trapped.

The grazing habits of cattle do not appear to be seriously restricted during the periods of greatest activity of the flies since at these periods grazing activity is also near maximum (see Table 2).

Table 2. MEAN PERCENTAGE OF CATTLE GRAZING BETWEEN DAWN AND DUSK DURING MONTHS APRIL AND MAY 1958

Local time	a.m. 7	8	9	10	11	12	p.m. 1	2	3	4	5	6	7
Percentage grazing	19	66	60	38	18	48	18	50	34	40	66	79	96

After three months of observation on two herds of young bullocks, one herd which is housed during the period mentioned shows a slight increase in live-weight gain over the herd left out continuously. The increase, however, is certainly not commensurate with the inconvenience and additional effort required for midday housing.

This investigation is being continued and in due course will be published elsewhere.

Intracellular Particles of Locust Fat Body

THE enzyme activities of insect mitochondrial preparations have been described in a number of papers[1–3]. I have observed that certain particle-bound enzymes in homogenates of the fat body of the desert locust (*Schistocerca gregaria* Forsk.) can be separated partially by differential centrifuging, and conclude that there are (at least) two distinct types of particles which resemble mammalian liver mitochondria and microsomes.

The tissue was taken from fifth instar nymphs on the fifth or sixth day of the eight-day stadium, freed of air sacs, washed once in cold water, drained on filter paper, and homogenized in 0·25 *M* sucrose solution at about 150 mgm. wet weight/ml.

The homogenate was centrifuged for 2 min. at about 600*g*, the upper layer of fat removed by suction, and the supernatant whole suspension decanted from the sediment of debris (and probably nuclei). The mitochondria were then sedimented from this suspension at 0° C. by spinning for 5 min. at 4,500*g*, and the supernatant carefully withdrawn and centrifuged at 14,000*g* for a further 30 min. at 0° C. The resulting clear supernatant was removed from the packed microsomes, and both particle fractions resuspended, without washing, in 0·25 *M* sucrose to the original volume of the whole suspension.

The whole suspension and the three fractions were tested for the following enzymes: (*a*) cytochrome oxidase (ref. 4, 2, 735); (*b*) fumarase (ref. 4, 1, 730); (*c*) Schradan-oxidizing enzyme, by rate of inhibition of endogenous phenyl esterase in the presence of supernatant or reduced triphosphopyridine nucleotide[5]; (*d*) aconitase, with citrate substrate (ref. 4, 1, 695); (*e*) isocitric dehydrogenase (ref. 4, 1, 699); and (*f*) phenyl esterase, by rate of liberation of *p*-nitrophenol from *p*-nitrophenyl acetate[6]. The results are expressed as percentages of the activity of the whole suspension in Table 1.

Table 1

Enzyme	Percentage activities		
	Mitochondria	Microsomes	Supernatant
Cytochrome oxidase	80	20	0
Fumarase	79	21	0
Schradan oxidizing	16	84	0
Aconitase	0	0	100
Isocitric dehydrogenase	0	0	100
Phenyl esterase	42	38	20

The mitochondrial fraction (sedimented at 4,500*g*) also contained some heavier particles which had none of the enzyme activities tested, but were distinguished by giving a red-brown colour with iodine and a positive Benedict's test only after incubation with saliva. They were presumed to consist of glycogen granules. They could be isolated by centrifuging a whole suspension at 14,000*g* for 30 min., when the sediment consisted of two clearly defined layers. The upper brown layer (mitochondria and microsomes) could be separated readily from the lower translucent grey one (glycogen-like material) by gently stirring with a small quantity of sucrose solution and decanting.

I am grateful to the Anti-Locust Research Centre for the locusts, and to Messrs. Fisons, Ltd., and the Agricultural Research Council for financial support.

Microvilli of the Cells of the Human Adrenal Cortex

IN the course of an electron microscopic survey of the human adrenal cortex an interesting specialization of the cortical cell plasma membranes was noted. Human adrenal cortex was removed at operation, fixed in 1 per cent isotonic osmic acid, embedded in methacrylate, sectioned by the standard technique on a thermal advance microtome, and examined in a Philips *EM* 100 microscope. Using parallel thick sections stained (Wright–Giemsa) and the light microscope, the different zones and cell types were readily identified.

In many of the cells of the zona fasciculata and zona reticularis, the plasma membranes form a complex arrangement of microvilli which project into the intercellular space in contact with similar microvilli of neighbouring cells (Fig. 1). The microvilli are tubular—150–200 A. in diameter—visible as circular and longitudinal profiles, and bounded by an osmophil single membrane with, at the relatively low resolution employed, a structureless centre (Fig. 2). The prominence of the villi varies at different points on the

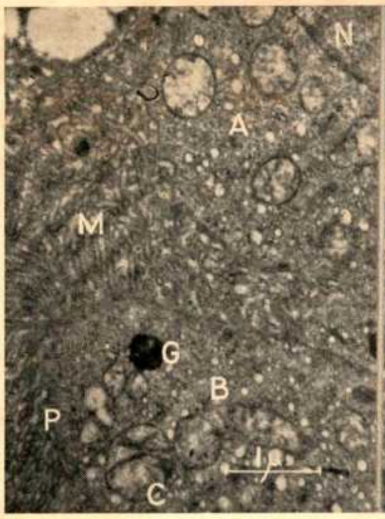

Fig. 1

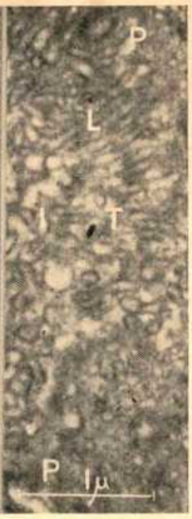

Fig. 2

Fig. 1. Section through zona reticularis of human adrenal. The intercellular space between cells *A* and *B* is occupied by microvilli *M*, which are clearly evaginations of the plasma membrane *P* of the cells. *N*, Nucleus; *C*, mitochondrion; *G*, lipid globule. (× 12,000)

Fig. 2. Section through microvilli cut in longitudinal (*L*) and transverse (*T*) section. *I*, Intercellular space; *P*, cell plasma membrane. (× 18,500)

cell surface; in the wide intercellular space at the junction of three or more cells the microvilli are longer and more numerous; where two cells are closely apposed the cell membrane tends to be smooth, while adjacent to blood sinuses it is merely imbricated (Fig. 3).

The cell processes of the human adrenal cortical cells are longer and more complex than similar processes described in the rat adrenal cortex[1] and in the parathyroid[2,3], and merit the description of microvilli, that is, something more than mere interdigitating extensions of cell membranes. Such structures are generally associated with the need for an increased absorptive surface; it seems likely that in the adrenal cortex that is also their function, and that they are in some way connected with the secretion of the steroid hormones.

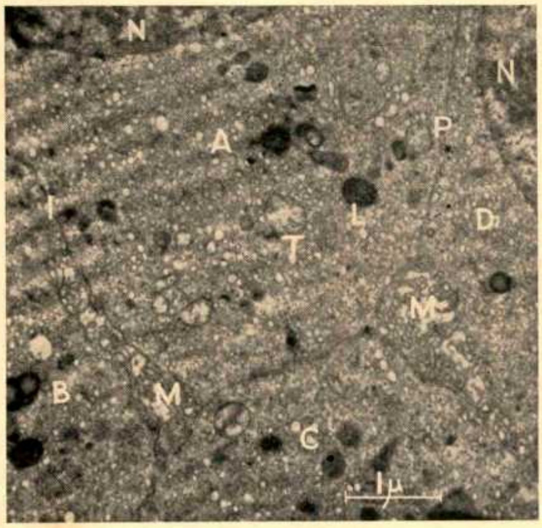

Fig. 3. Section through four cells (*A*, *B*, *C*, *D*) of zona reticularis. The plasma membranes are plane (*P*) or imbricated (*I*) where only two cells are in contiguity, but are thrown into microvilli (*M*) where the intercellular space is bigger. *N*, Nucleus; *T*, mitochondria; *L*, lipoid globules. (× 12,500)

Another characteristic of the human adrenal cortex is the clear distinction, at the electron microscopic level, between the cells of the zona reticularis and those of the zona fasciculata. The former contain relatively few lipoid granules, but larger and more numerous mitochondria as compared with those of the latter.

Enteroviruses in the Pig

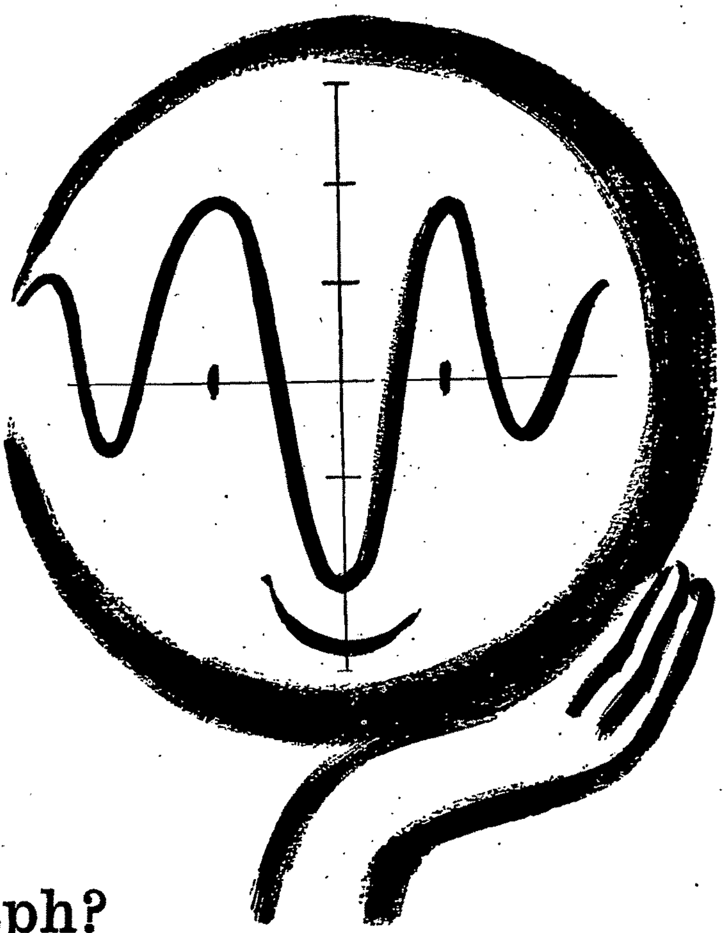
IN recent years, many viruses have been recovered from the alimentary tract of man and the term 'enteroviruses' has been proposed[1] as a group name for them. The enterovirus group comprises the three strains of poliomyelitis virus, the Coxsackie viruses and the Echo (enteric cytopathogenic human orphan) viruses. The Echoviruses have not yet been conclusively associated with specific clinical conditions and it is not at present possible to determine their exact significance as causes of disease in man. Using tissue culture techniques attempts are being made in this laboratory to determine whether viruses comparable to the human enteroviruses occur in the alimentary tract of pigs.

The tissue-cultures used have been stationary monolayer cultures prepared from renal cortical tissue of the pig by a modification of Bodian's trypsinization method[2] and grown in a medium consisting of calf serum (20 per cent) and lactalbumin hydrolysate (0·5 per cent) in Hank's balanced salt solution with antibiotics. Before inoculation, the growth medium has been replaced with a maintenance medium consisting of calf serum (5 per cent) and lactalbumin hydrolysate (0·5 per cent) in Earle's balanced salt solution with antibiotics.

From the first thirteen fæces samples examined three immunologically distinct cytopathogenic agents have been recovered. One of these agents was isolated from an outbreak of a disease clinically similar to Talfan disease[3] (Teschen disease or poliomyelitis suum). This agent was neutralized by antisera to Talfan disease, kindly supplied by Mr. J. T. Done.

Another agent, one which has been studied in some detail, was recovered from fæces collected from pigs in a herd in which enteritis was a severe problem.

This virus causes a cytopathogenic effect in pig kidney cells similar to that caused by poliomyelitis in human or simian kidney cultures. The effect appears 3–5 days after inoculation but the increase in virus titre precedes this by 24 hr. Titres are of the order of 10^5 tissue-culture *ID*50 per ml. of tissue-culture fluid. The virus will pass through 'Gradocol' membranes having an average pore diameter of 100 mμ, but not through membranes with an average pore diameter of 55 mμ; preliminary electron-microscope studies show a particle of diameter of the order of 35 mμ. The agent is resistant to ether; it is inactivated within 2 min. at 56° C., within 100 hr.



Thinking about an oscillograph?

If you are experienced in the design of high quality instruments; our Technical Director would be glad to hear from you.

FOR USE IN ELECTRONICS? From the wide range of single and double-beam instruments, a model is available to suit the requirements of all sections of this expanding industry.
IN INDUSTRY? Diverse industries are finding solutions to their design and production difficulties with the aid of the Cathode Ray Oscillograph. Our Technical Advisory Service will be pleased to help you with your specific problem.
IN SPECIALISED FIELDS? Unusual types of oscillograph have been designed for specialised applications in the Hydraulic, Marine and Ultrasonic fields. We shall be pleased to consider specific development projects.

PHONE: ARCHWAY 2270.

at 37° C., but will survive more than three weeks at room temperature. It is easily preserved by storage at − 68° C. and can be successfully freeze-dried. Formaldehyde, at a concentration of 0·009 per cent, inactivates 90 per cent of the virus in 30–48 hr. Attempts to cause a cytopathogenic effect in bovine kidney and human epithelial cells (strain HeLa) have failed, as have attempts to adapt the virus to growth in embryonated hen's eggs.

Several attempts to infect pigs have been made with tissue-culture fluids containing virus. In all cases the experimental pigs were colostrum-deprived, 'disease-free' piglets obtained by hysterectomy following the methods of Young and Underdahl[4,5]. Various routes of inoculation were tried but the only clinical response obtained was a transient rise in temperature accompanied by a slight diarrhœa. Attempts to potentiate the response with cortisone were unsuccessful. No pathological changes were found on post-mortem examinations. The virus has been recovered from the fæces of these experimentally infected pigs, while sera from all of them showed an increase in neutralization index of more than 1,000-fold.

Studies on this virus are still in progress and will be reported in detail elsewhere.

Light and Dormancy in Wild Oats (*Avena fatua* L.)

Recently, inhibitory effects of white light on germination of wild oats with natural dormancy[1,2] and with dormancy induced by previous immersion in water[3] have been reported. To test the effect of quality of light on the germination of wild oats, white light at 440 foot-candles was provided by tungsten plus standard cool white fluorescent lamps. Infra-red filters and coloured 'Cellophane' were used to isolate the blue, red and infra-red parts of the spectrum. The temperature in each Petri dish was 24·5 ± 0·5° C.

Table 1 shows that none of the light treatments inhibited germination of non-dormant wild oats or wild oats with dormancy broken by removing the hulls and then puncturing the seed coats. However, white, blue and infra-red radiation markedly inhibited germination of partially dormant wild oats. Seeds of the lettuce var. Grand Rapids (about which much is known regarding light sensitivity[4]) were also exposed to the same conditions for comparison. Blue and infra-red radiation strongly inhibited germination of the lettuce seeds whereas red and white caused slight stimulation. Although the latter increases were small they were found consistently. Thus, red light was without effect on wild oat germination but it stimulated lettuce seed germination. White light, on the other hand, was decidedly inhibitory to wild oats but not to lettuce.

Table 1. PERCENTAGE GERMINATION OF WILD OATS AND LETTUCE FIVE DAYS AFTER INHIBITION, EXPOSED TO WHITE, BLUE, RED AND INFRA-RED RADIATION AND DARKNESS. CONTINUOUS LIGHT SOURCE. TEMPERATURE, 24·5 ± 0·5° C.

Condition of seed sample	Quality and energy (gm. cal. cm.$^{-2}$ hr.$^{-1}$) of radiation White (440 f.c.)	Blue	Red	Infra-red	Darkness
Non-dormant wild oats	97·5	100	100	100	97·5
Dormant wild oats	28·0	14·0	60·0	8·0	66·0
Dormant wild oats—dehulled then pricked	100	100	100	100	100
Lettuce var. Grand Rapids	77·0	1·5	81·0	3·0	68·5

Similar results were obtained in other tests on wild oats conducted with white light ranging from 300 to 1,500 foot-candles and at temperatures between 20 and 25° C. The response was similar under either short or long days, or continuous light.

Little attention has been given to the effect of light on the germination of weed seeds under natural conditions. To study the effect of daylight on the germination of wild oats, partially dormant and non-dormant seeds were planted on the soil surface and at a depth of 1 in. in wooden flats. One set of flats was placed in a confined space in darkness and watered frequently to maintain high humidity at the soil surface. Other flats were placed outdoors in direct sunlight; in one treatment the air above the soil surface was kept moist by an intermittent mist spray (relative humidity not less than 95 per cent), in the other the soil surface was watered at the start and then left under prevailing natural conditions (control).

Table 2 shows that there was virtually complete germination of non-dormant seeds on the surface and at a depth of 1 in., both in sunlight and in darkness. In contrast, with the partially dormant seeds in light, there was only 10 per cent germination at the soil surface, whereas 65 per cent germinated at the 1-in. depth. That the inhibitory effect on the soil surface was due to light is shown by the fact that 55 per cent germination was obtained on the surface in the dark. (The lower germination of partially dormant seed at 1 in. in darkness was afterwards found to be due to excessive watering, which was inhibitory to germination below the surface; this does not alter the conclusion that light inhibited germination at the surface).

These experiments show that, under artificial conditions, white, blue and infra-red radiation inhibit germination of partially dormant wild oats. Under natural conditions, daylight inhibits the germination of partially dormant wild oats on the soil surface; cultivations that bury such seed may therefore favour increased germination. Recent field tests have shown that, when autumn tillage was practised, wild oats

Table 2. PERCENTAGE GERMINATION OF DORMANT AND NON-DORMANT WILD OATS, PLANTED ON SOIL SURFACE AND AT 1-IN. DEPTH. PLANTED SEPTEMBER 15, 1957; DATA RECORDED, SEPTEMBER 23, 1957

Condition of seed sample	Depth planted	Darkness: High relative humidity*	Normal daylight: High relative humidity*	Normal daylight: Control
Non-dormant	Surface	95	98	85
	1 in.	98	100	97
Dormant	Surface	55	10	1
	1 in.	23	65	64

* High relative humidity = not less than 95 per cent.

germinated earlier and in greater numbers the following spring[5].

Effect of Gibberellic Acid on Corolla Size

IN a previous communication[1] I reported that emasculation of *Glechoma hederacea* flower buds resulted in a reduction in corolla size similar to that found in naturally occurring female flowers, and I suggested that the anthers produced a hormone causing enlargement of the corolla. An attempt to replace this by the application of β-indolylacetic acid to emasculated buds was ineffective—low concentrations having no effect and high concentrations (500 and 1,000 p.p.m.) causing inhibition of corolla growth.

This year I have tested α-naphthaleneacetic acid, 2 : 3 : 5-tri-iodobenzoic acid and L-proline (cf. ref. 2), and found that they did not affect corolla size except at high concentrations, when they were inhibitory.

Dr. S. Housley suggested the use of gibberellic acid and this proved effective. When applied in aqueous solution to emasculated buds it restored the size of the corolla to that of intact flowers (the results of one experiment are given in Table 1). A small increase also resulted from treatment of intact hermaphrodite buds with gibberellic acid.

Table 1. EFFECT OF GIBBERELLIC ACID (10 P.P.M.) ON EMASCULATED AND INTACT HERMAPHRODITE FLOWER BUDS OF *Glechoma hederacea*

Treatment	No. of flowers measured	Mean length of mature corollas (mm.)
Emasculated. Gibberellic acid inserted	8	19·6
Emasculated. Distilled water inserted	12	15·9
Intact. Gibberellic acid inserted	14	21·3
Intact. Distilled water inserted	14	19·4

Treatment of natural female flowers caused a striking enlargement of the corolla, producing flowers of about the same length as intact hermaphrodites (Table 2).

Table 2. EFFECT OF GIBBERELLIC ACID (10 P.P.M.) ON NATURAL FEMALE FLOWER BUDS OF *Glechoma hederacea*

Treatment	No. of flowers measured	Mean length of mature corollas (mm.)
Gibberellic acid inserted	12	19·1
Distilled water inserted	12	13·4

The situation appears to be comparable with that in dwarf peas, which are converted into tall peas by gibberellic acid but are unaffected by auxin alone[3].

The effect of emasculation and its reversal by gibberellic acid may be general phenomena. I have obtained results from *Geranium anemonifolium* similar to those from *Glechoma*.

Full details of the work will be published elsewhere.

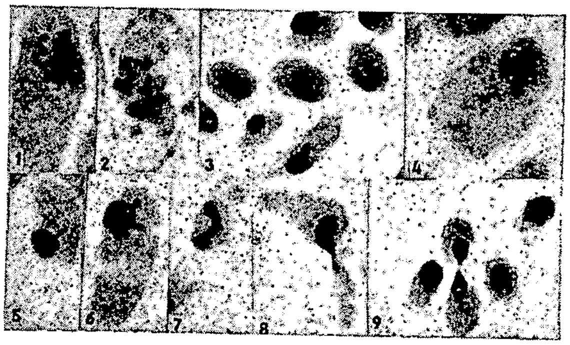
Kinetics of Mitosis in Yeasts

WHILE differences of opinion still exist among yeast cytologists concerning the real significance of the vacuole and the chromosome number of different yeast species, it is clear from the work of De Lamater[1], Lietz[2], Winge and Roberts[3], Lindegren *et al.*[4] and McClary *et al.*[5] that (*a*) during division the yeast nucleus resolves into chromosomes which can be identified by suitable techniques; (*b*) the nuclear membrane persists throughout the division cycle, whereas in higher organisms the membrane disappears in the prophase and reforms in telophase; and (*c*) intra-nuclear mitosis is followed by a process of nuclear separation and movement into the daughter cell which simulates amitosis. Doubt whether nuclear division is amitotic[6,7] could thus arise when no distinction is made between the nuclear division proper and the transport of the daughter nucleus into the bud. We have studied the nuclear cytology of the vegetative diplophase of *Saccharomyces cerevisiae*, *Zygosaccharomyces priorianus* and *Schizosaccharomyces pombe*, using a new technique[8], and the course of mitosis and the mode of separation of daughter nuclei observed by us are described here.

Division phase. At the onset of mitosis the nucleus is resolved into chromosomes, and configurations resembling the prophase and metaphase chromosomes of other organisms could be seen in squash preparations (Figs. 1 and 2). The exact chromosome number



Figs. 1–9. Giemsa preparations of mitotic stages in *S. cerevisiae*. (1) Prophase. (2) Metaphase. (3) End of intranuclear mitosis. A double structure in some nuclei and single and divided centrosomes are seen. One cell with the smaller nucleus has apparently not yet entered mitosis. (4) A nucleus with a single centrosome. (5) and (6) Beginning of the separation of the divided halves of the nucleus. Two centrosomes are seen. (7) A near dumbbell configuration. (8) One nucleus passing into the bud. The centrosome is seen entering the bud first. (9) Final stage in the separation of nuclei

is, however, not clear. We have seen eight chromosomes (Fig. 2) in some, but not in all cells. The difficulty in getting consistent pictures of chromosomes arises largely from the persistence of the nuclear membrane. Metaphase is followed by anaphase, in which the two chromatids of each chromosome seem to go to opposite poles ; telophase then sets in. We have never observed directly anaphase and telophase within the nuclear membrane, but the pattern of staining and the appearance of unstained regions within the nucleus suggest that these stages follow metaphase. It also appears that the telophase is prolonged, since nuclei appearing double are commonly seen (Fig. 3). A single centrosome is also seen at this stage (Fig. 4).

Separation phase. The centrosome divides into two at the end of the intra-nuclear mitosis. This is followed by the appearance of a small median constriction in the nuclear membrane between the centrosomes (Fig. 5). This constriction proceeds by furrowing and leads to a partial division of the divided nucleus. The extension of such furrowing results in the two partially divided halves of the nucleus, each provided with a centrosome, moving apart (Figs. 6 and 7). During this gradual movement, the nucleus assumes several shapes. The two centrosomes with their respective halves usually turn through 180°, resulting finally in a dumb-bell configuration. It appears that the angle of movement of the two separating halves may, however, vary—depending upon the relation between the plane of division and the position of the bud. Perfect dumb-bell configurations occur only when the angle is 180°, which happens in a majority of cases. The final separation of the daughter nuclei occurs when the nuclear membrane is stretched to the maximum. When this final separation occurs, one daughter nucleus is found in the bud and another in the mother cell (Figs. 8 and 9). If, however, the bud is far away from the plane of nuclear division or has not yet been formed, both the daughter nuclei may be found in the same mother cell. This scheme of nuclear division and separation is diagrammatically represented in Fig. 10, together with the schemes postulated by De Lamater[1], Lietz[2], and Lindegren *et al.*[4].

The method of nuclear fission and separation of daughter nuclei described above seems to be characteristic of *S. cerevisiae* in which there is apparently no synchronization in time between the appearance of the bud and any particular stage of mitosis. Neither is there any correlation between the point of origin of the bud and the plane of nuclear division. In *Schizosaccharomyces pombe*, cytokinesis is of the type seen in higher plants and the constriction in the nuclear membrane appears to start from both the ends, with the result that the different shapes of nucleus observed in *S. cerevisiae* during the separation phase are not seen. Mitosis is, however, intra-nuclear in all the yeasts studied by us.

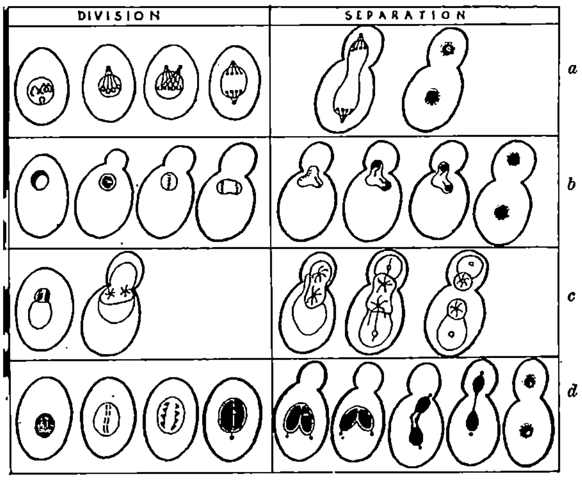


Fig. 10. Nuclear division and separation according to: *a*, De Lamater (ref. 1); *b*, Lietz (ref. 2); *c*, Lindegren *et al.* (ref. 4); *d*, the present authors.

De Lamater[1], Lietz[2], and Lindegren *et al.*[4] have used the terms 'anaphase' and 'telophase' to designate stages in the separation of the daughter nuclei, thus confusing the intra-nuclear separation of the divided chromosomes with the separation of the daughter nuclei by furrowing and subsequent movement. As a consequence, their schemes will demand both some form of synchronization between budding and anaphase of mitosis, and a localization of the point of origin of the bud with the plane of nuclear division. The doubling observed in many yeast nuclei at the end of mitosis but before separation of the daughter nuclei, as well as the lack of any relationship between budding and nuclear separation either in time or in plane of movement, supports our view that anaphase and telophase are actually completed within the nuclear membrane, thus effecting the regular distribution of the divided chromosomes prior to the initiation of a process analogous to cytokinesis in the nucleus.

We are indebted to Dr. B. P. Pal and Dr. S. M. Sikka for their interest in the study. Our thanks are also due to Prof. Ö. Winge and Dr. Catherine Roberts, of the Carlsberg Laboratory, Copenhagen, for critical advice on the manuscript.

Heat as an Agent producing High Frequency of Mutations and Unstable Genes in *Escherichia coli*

MILD heating (up to 36° C.) is known to produce a small increase of the spontaneous mutation-rates in *Drosophila* and in bacteria. We have found that using special conditions it is possible to have mesophilic non-sporogenic bacteria (*Escherichia coli*) survive relatively high temperatures (60° C.) ; this sub-lethal treatment produces a high frequency of mutations and unstable genes.

Mutants of strain 15 (A.T.C.C. 9723) and of strain *W*6 ($F+$, mutant of $K12$)[1], yielding more survivors after heating (as below), have been isolated. 24- to 30-hr. old (37°) cultures in nutrient broth were heated by totally submerging stoppered tubes in a constant-temperature bath. In another procedure

Table 1. Stable and Unstable Mutants produced by Heat

Parent strain	Treatment	Survival (per cent)	I.C.*	Mutants			
				No. of different mutants	Description	Frequency	Stability
15 (heat resistant)	2 hr. 60° in sucrose	2×10^{-2}	+	2	Thiamine⁻	10^{-3}	Stable
	4 hr. 60° in sucrose	3×10^{-4}	+	3	'Pinpoint'	10^{-2}	Stable
	2–4 hr. 55°	2×10^{-2}–5×10^{-3}	−	4	Lactose⁻, maltose⁻	4×10^{-3}–5×10^{-2}	Stable†
	4 hr. 55°	5×10^{-3}	−	5	Partial lactose⁻	10^{-1}	Stable
	4 hr. 55°	10^{-3}	+	1	Glucose⁻, lactose⁻	2×10^{-2}	Unstable
	3–4 hr. 60° in sucrose	10^{-2}–3×10^{-4}	+	6	'Pinpoint'	10^{-2}–5×10^{-3}	Unstable
	4 hr. 55°	10^{-2}	+	4	'Pinpoint'	10^{-3}	Unstable
W6 (heat resistant)	½ hr. 60° in sucrose	6×10^{-5}	+	1	Purine⁻, thiamine⁻	10^{-3}	Stable
	2 hr. 60° dried	3×10^{-4}	+	2	'Pinpoint'	2×10^{-3}	Stable
	½ hr. 60° in sucrose	6×10^{-5}	+	2	'Pinpoint'	2×10^{-3}	Unstable

* Intermediate cultivation: None (−), or 18 hr., 37° in nutrient broth (+).

† Spontaneous 'back-mutation' (mutation-rate 3×10^{-11}) to lactose⁺, maltose⁻, to lactose⁺, maltose⁺; also directly to lactose⁺, maltose⁺

the cultures were suspended in 50 per cent sucrose, incubated for 2 hr. at 30° and then heated as above. In still another procedure the cultures were centrifuged, the pellet was dried in vacuum over phosphorus pentoxide for 2 hr. and then heated as above.

The survivors (Table 1) underwent phenotypic damage, which probably includes heat denaturation of synthesizing enzymes: after 3 hr. heating at 60° (strain 15 in sucrose), the survivors, which form colonies of various sizes on nutrient agar (non-hereditary changes), are unable to grow on minimal agar. This inability is also non-hereditary ('pseudo-auxotrophs').

The surviving populations in all heating experiments were searched for mutants by streaking on nutrient agar, Endo's agar, or minimal agar containing 0·05 per cent proteose peptone, either directly after heating or after intermediate cultivation in nutrient broth. The populations contained a very high proportion of mutants (Table 1). This high proportion already makes it unlikely that the mutants were present in the original populations and merely selected by heat treatment. However, to exclude further this possibility, several mutants were mixed with the original population and tested for survival in the same heating conditions. All these mutants were less resistant to heat than the original population, which indicates that the mutants were produced by heat and not selected by it. Similarly, the selection of mutants during the intermediate cultivation was excluded by the demonstration that the mutants grew more slowly in the nutrient broth than the original population. Thus, the actual mutation-rates may be higher than those which can be calculated from the mutant frequencies in Table 1.

The mutants isolated to date (Table 1) include those that occur spontaneously or can be readily induced by previously known agents as well as those rarely obtained by other means. Repeated incidence of thiamine⁻ mutants from different parent strains may also be unusual. Of particular interest are the unstable mutants, similar to the one which has occurred in unidentified circumstances[2] or to those which can be induced by 5-bromouracil in conditions of its incorporation into deoxyribonucleic acid of the cells[3]. The unstable mutants obtained by heating were isolated after intermediate cultivation as undersized colonies on nutrient agar; they mutated to 'pinpoint' colonies with high frequencies (of the order of 2×10^{-2}–10^{-1}); some of the 'pinpoints' were stable mutants whereas others mutated again to colonies of normal size (mutant frequencies 3×10^{-2} to 7×10^{-1}); some of the latter gave stable strains whereas others mutated again to 'pinpoint' colonies. At least four 'pinpoint' strains might be partially deficient nutritional mutants (full size colonies on richer N.I.H. agar ('Difco').

As mentioned before, some of the mutants induced by heat (non-fermenters, auxotrophs) are similar to known 'segregating' ('nuclear', 'chromosomal') mutants. This suggests that the heat-induced markers (mutants) are also 'segregating' rather than 'cytoplasmic'. However, more rigorous proof was desirable. To this end, a heat-induced purine⁻, thiamine⁻ mutant of strain *W6* was crossed with strain 1177 (*F*⁻, thiamine⁻)[1]. Out of 2,000 recombinants on minimal agar containing thiamine, 11 were isolated that were purine⁻; in addition, when a thiamine+ mutant of 1177 was used as *F*⁻, 1 per cent of recombinants was both adenine⁻, thiamine⁻; these results clearly indicate the 'segregational' nature of this heat-induced mutant. However, it is not unlikely that in addition to the segregating mutants studied here, heat treatment can also produce the non-reversible cytoplasmic mutants or some other unknown disturbances in the orderly process of heredity transmission.

From the foregoing, it is apparent that the mutagenic and unstabilizing effect of heat is of a different magnitude than that of other microbial mutagenic agents, with the exception of 5-bromouracil in the conditions of its incorporation into deoxyribonucleic acid[3]; as in the case of 5-bromouracil, heat as a mutagenic agent has the advantages that one can be sure that it reaches deoxyribonucleic acid and that the actual changes induced by it in this substance have been studied by physico-chemical methods. It has been suggested that the first action of the mutagenic agent is to bring the gene into an unstable state; if so, then the 'unstable mutants' are those which have not lost their instability after having mutated. If the role of cellular deoxyribonucleic acid is the determination of heredity, then its unstabilization is a likely cause of gene unstabilization. The unstabilization *in vitro* of deoxyribonucleic acid having transforming activity by heat has been demonstrated[4]; the conditions used were not much more drastic than those in the present work. Individual heredity determinants of the same cell have different stabilities towards heat[5]; it is not unlikely that some of them undergo unstabilization upon prolonged heating even at 55° or 60°. The demonstration that at least one heat-induced mutant is segregating ('chromosomal' mutation) also suggests that the damaged heredity determinant may be deoxyribonucleic acid.

This investigation was supported by research grants from the National Institutes of Health, American Cancer Society and National Science Foundation. The abstract of a part of it has been presented[6].

Desiccation of Eggs of the Crane Fly (*Tipula oleracea*, L.)

THE ease with which crane fly eggs lose water is of some ecological importance since the eggs are laid near the surface of the soil, among the bases of the grass stems. In this position they are likely to experience fairly wide fluctuations in humidity, at least during drought periods.

The egg is black, measures about 0·8 mm. by 0·3 mm. and has a long, thin filament attached to one end. The incubation period is six days at 21° C. The newlaid egg looks shrunken and wizened. After 5–10 min. it becomes slim and rounded. By the third day it has absorbed water and become considerably bigger.

Using the filament, eggs were suspended in dry air and observed. The first sign of collapse is a slight flattening of one side, closely followed by the appearance of a dimple. The time taken for the dimple to appear was recorded for eggs of different ages. This measurement could be important physiologically since the collapse of the shell might be expected to cause mechanical damage to the embryo.

Eggs up to 15 min. old dimple in 2–4 min. At 15 min. old the dimpling time increases sharply to between 10 and 25 min. It increases steadily thereafter and by the sixth day eggs take 1–1½ hr. to dimple.

Eggs of different ages (5 min., 1 hr., 1 day and 4 days) were then exposed to dry air for about three times the dimpling time at their respective ages. All survived. Another group of eggs, 1 hr. old, were exposed for 100 min. (five times the dimpling time) and only 35 per cent survived. Another experiment showed that eggs more than 1 day old can survive about 1 day at 75 per cent and 2–3 days at 90 per cent relative humidity.

Two interesting points emerge from these preliminary experiments. The egg can survive considerable mechanical deformation. After the first day eggs are able to stand quite severe conditions for at least 24 hr. (and humidities of less than 95 per cent, particularly in the grass mat, are likely to prevail for no longer than the daylight hours).

It seems likely, therefore, that in the field the egg runs little risk of death from desiccation except at the beginning of the embryonic period.

Full details of these and further experiments on the water relations of the crane fly egg will be published elsewhere.

W. H. Perkin and the Young Chair of Technical Chemistry in the Royal College of Science and Technology, Glasgow

IN evidence on technical education given before the Select Committee on Estimates on June 19, 1953, and published in its twelfth report for the session 1952–53, Dr. (now Sir) D. S. Anderson, director of the Royal Technical College, Glasgow, mentioned that Prof. W. H. Perkin, of dye fame, had been a professor there. Afterwards, in an article on the Royal Technical College, Glasgow, in the *Journal of the Royal Institute of Chemistry* in 1954, Dr. J. A. Cranston, after stating that in 1870 James Young, who was at that time president of Anderson's University, founded the chair of technical chemistry which bears his name, giving 10,000 guineas to endow what was the first chair of applied chemistry in the United Kingdom and further sums of money to provide suitable buildings and fittings, added: "The first 'Young' Professor of Technical Chemistry, 1870–71, was William H. Perkin, discoverer of mauve dye and founder of the coal-tar colour industry".

This is not mentioned in any of the obituary notices of Perkin, and accordingly I made further inquiry of Sir David Anderson when preparing a paper on Perkin and the dyestuffs industry in Britain. In consequence, Sir David and the College librarian made further search into the matter. It appears that although the chair was offered to W. H. Perkin in September 1869, Prof. Penny, the then professor of chemistry, formally protested against the nomination and appointment of an additional professor of chemistry in, or in connexion with, Anderson's University, as adversely affecting his privileges and interests. As a result, Mr. Young withdrew the grant and asked the trustees to allow him to cancel the deed of foundation, and in July 1870 agreed to a modification of the trust deed to secure harmonious working with the existing chair of chemistry. The modified deed and the donation of £10,500 were accepted by the trustees of Anderson's University at a special meeting on July 12, 1870. Perkin's name is not mentioned in connexion with the new negotiations, so either the offer was not renewed or in the meantime he had definitely declined.

For reasons of space, no reference was made to this episode in my article in *Nature* of May 5, 1956, p. 815; but since in his recent history of the chemical industry, Haber (p. 75) writes, "James Young . . . endowed the Young Chair of technical chemistry at Anderson's University, of which he was one of the most distinguished graduates, in 1870. W. H. Perkin was the first professor, from 1870 to 1875, and was succeeded by E. J. Mills", it seems desirable to place the facts on record without further delay.

R. BRIGHTMAN

Red Lodge,
Cow Lane,
Norley, Cheshire.

FORTHCOMING EVENTS

Sunday, August 31—Wednesday, September 3

British Association for the Advancement of Science (at Glasgow).—Continuation of Annual Meeting.

Sunday, August 31

At 11 a.m.—(in Glasgow Cathedral)—Religious Service. Preacher: The Reverend Dr. Nevile Davidson, Minister of Glasgow.

Monday, September 1

At 10 a.m.—Dr. T. E. Allibone, F.R.S.: "Some Aspects of Thermonuclear Power" (Presidential Address, Section A).

At 10 a.m.—Prof. L. R. Wager, F.R.S.: "Beneath the Earth's Crust" (Presidential Address, Section C).

At 10 a.m.—Dr. Iorwerth C. Peate: "The Study of Folk Lore and Its Part in the Defence of Civilization" (Presidential Address, Section H).

At 10 a.m.—Dr. E. N. Willmer: "Some Aspects of Cellular Differentiation" (Presidential Address, Section I).

At 8 p.m.—Dr. C. F. A. Pantin, F.R.S.: "Living Machinery and the Electron Microscope" (Evening Discourse).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Lecturers and Lecturers (with a degree or equivalent qualifications with suitable teaching and professional qualifications) in the Department of Mechanical Engineering, Kumasi College of Technology—Council for Overseas Colleges, 12 Lincoln's Inn Fields London, W.C.2 (September 5).

Assistant, Grade *B* (preferably with experience in industry, teaching and/or research) in General Chemistry—The Principal, Nottingham and District Technical College, Burton Street, Nottingham (September 6).

Research Assistant (with a good degree in chemistry or biochemistry, and preferably some research experience or qualification) in the Zoology Department, to investigate effects of chemical pollutants on marine organisms—The Secretary and Registrar, The University, Southampton (September 6).

Research Assistant (with a good honours degree, a knowledge of German and ability to draw maps) in the Department of Geography—The Registrar, The University, Leeds 2 (September 8).

Lecturer or Assistant Lecturer (preferably with some experience of X-ray crystallography) in Physics—The Registrar, The University, Sheffield (September 13).

Tutorial Research Student in Zoology—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (September 15).

Research Assistant (with a good honours degree in physics and some research experience) in the Department of Physics, to take part in research which is at present concerned with X-ray diffraction, physical optics, electronics and instrumentation—The Registrar, Manchester College of Science and Technology, Manchester 1 (September 20).

Keeper (with a good honours degree and preferably with the Diploma of the Museums Association) in the Department of Botany, Manchester Museum—The Registrar, The University, Manchester (September 30).

Lecturer (Grade I or II) (with interests in entomology or physiology) in Zoology at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 30).

Senior Lecturer or Lecturer in Mathematics at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 30).

Soil Microbiologist (Mycologist) (with a good honours degree), for work on isolation and identification of possible vectors of soil-borne viruses; and an Entomologist/Virologist (with a good honours degree), for work on problems of virus transmission—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, by Dundee (October 4).

Managing Director (with high level administrative experience together with a wide knowledge of the sciences and their industrial application, or proved ability to provide administrative leadership for a technological team) of the National Research Development Corporation—The Secretary, Board of Trade, Horse Guards Avenue, London, S.W.1, marking envelope "N.R.D.C. Application" (October 13).

Senior Lecturer in Mathematics at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 31).

Assistant Experimental Officer (with a suitable degree, G.C.E. with chemistry at advanced level, or equivalent qualifications) in the Chemistry Department, to help with research work on the composition of milk, milk products, feeding stuffs, etc.—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 58/22.

Fisheries Officer (male, with a university degree in natural science (zoology) and preferably some experience of fishery administration) in Aden, to organize and develop the domestic fisheries of the Colony and Protectorate—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/2/01.

Lecturer in Mechanical Engineering, and a Lecturer in Mining Geology at the University of Rangoon, Burma—The Ministry of Labour and National Service (E.9), 26–28 King Street, London, S.W.1, quoting Ref. E.9/TCS/234-5-8/BUR.

Livestock Improvement Officer (with a university degre agriculture and considerable knowledge and experience of crop animal husbandry) in Gambia, to investigate fodder resources subsequently initiate a programme of work designed to establi mixed farming system of agriculture—The Director of Recruitn Colonial Office, London, S.W.1, quoting BCD.63/12/13.

Research Assistants in (*a*) Physics, and (*b*) Telecommun tions—The Clerk to the Governors, Woolwich Polytechnic, Lon S.E.18.

Research Officer (Biologist) (with a good honours degre zoology, a knowledge of marine biology, particularly fishes plankton, with preference and aptitude for work at sea) with East African Marine Fisheries Research Organization, Zan: —The Director of Recruitment, Colonial Office, London, S. quoting BCD.195/194/03.

Senior Experimental Officer (at least 35 years of age, wi pass degree, H.N.C., or equivalent qualification, and familiar high voltage laboratory techniques and pulse circuitry), to be sponsible for the construction of high energy condenser banks desi to produce very heavy current gas discharges—The Senior Rec ment Officer, Atomic Weapons Research Establishment, Alderma Berks, quoting Ref. 1963/2.

Senior Lecturer in Chemical Engineering, and a Se Lecturer in Metallurgy at the University of Rangoon, Burn The Ministry of Labour and National Service (E.9), 26–28 King St London, S.W.1, quoting Ref. E.9/TCS/236-7/BUR.

Using a radio-isotope (contained in the axial tube) to radiograph the welded seams in a cylindrical pressure vessel. Ilford Industrial X-ray films, held in flexible cassettes, are attached to the outside of the cylinder. Reproduced by courtesy of G. A. Harvey & Co. (London) Limited.

Photography in the Nuclear Age

More power for industry means increased prosperity for the nation. And so it is, as the programme for building nuclear generating stations goes ahead, that photography, with its partner, radiography, has a stake in Britain's future. For here is a vast co-operative effort in which many of the problems of research, design and construction depend for a solution on photographic methods.

Throughout the whole of this important field, Ilford sensitised materials render invaluable service which extends from helping to reveal the secrets of the atom to the vital task of testing the soundness of welded pressure vessels.

LECTURES AND COURSES

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S.W.3
DEPARTMENT OF CHEMISTRY
SESSION 1958-59

A course of 20 postgraduate lectures on "Biochemistry" (to be arranged in four groups) will be given by Dr. E. M. Crook, M.Sc., and Professor F. L. Warren, M.A., D.Sc., on Mondays, 7.15 to 8.30 p.m., during the period October 6, 1958, to March 16, 1959. The course is designed for students who possess a knowledge of chemistry to degree standard. Fee: £2 for whole course or 10s. for each group.

A leaflet giving details is obtainable from the Secretary.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S.W.3
DEPARTMENT OF GEOLOGY
Head of Department: W. E. Smith, M.Sc., F.G.S.
ORE-DRESSING

A course of ten lectures on the mineralogical aspects of ore-dressing will be given by Dr. E. Cohen on Wednesday evenings during the Autumn Term. 1958. The course is intended for graduates in Geology and metallurgists with a basic knowledge of mineralogy.

Further information may be obtained from the Head of the Department.

THE POLYTECHNIC

309 REGENT STREET, W.1
DEPARTMENT OF MATHEMATICS AND PHYSICS

The following courses of lectures have been arranged, starting in September, 1958:

1. MATHEMATICAL STATISTICS
   on Tuesday, Thursday and Friday evenings.
2. ADVANCED MATHEMATICS FOR SCIENTISTS AND ENGINEERS
   on Wednesday evenings.
3. MODERN ELECTRIC NETWORK THEORY
   on Friday evenings.
4. FINITE DIFFERENCE EQUATIONS AND DIFFERENCE-DIFFERENTIAL EQUATIONS
   on Monday evenings.
5. INTEGRAL EQUATIONS AND GREEN'S FUNCTIONS
   on Wednesday evenings.
6. AUTOMATIC DIGITAL COMPUTERS
   on Tuesday evenings.
7. ELECTRONICS
   on Monday, Wednesday and Thursday evenings.

Full particulars may be obtained on application to the Director of Education.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

LONDON, S.W.7
CHEMICAL ENGINEERING DEPARTMENT
POSTGRADUATE COURSES IN INDUSTRIAL SAFETY

Full- and part-time courses in Industrial Safety (with particular reference to the Chemical Industry) arranged under the direction of Dr. J. H. Burgoyne, will be available for graduates in Chemistry, Chemical Engineering and related subjects during the session commencing October 1, 1958.

Further particulars from the Registrar, Imperial College, London, S.W.7.

SHORT POSTGRADUATE COURSES IN Chemical Physics, suitable for graduate students or for research workers in related fields, will be held during the 1958-1959 Session. The Courses are of 5 to 12 lectures' duration and deal with the following topics: rate processes in solids, electronic properties of solids, crystal growth, rate processes in liquids, and the thermodynamics of liquids, gases and solutions.—Further information from the Registrar, Imperial College, London, S.W.7.

OFFICIAL APPOINTMENTS

UNIVERSITY OF SHEFFIELD

Applications are invited for a post of Research Assistant to the Professor of Mining, to begin duties as soon as possible. Salary up to £800 with F.S.S.U. provision and family allowance. Applicants should have a good degree in mining, engineering or pure science.

Further particulars should be obtained from the Registrar, to whom applications (four copies) should be sent by September 20, 1958.

UNIVERSITY OF LEEDS

UNITED LEEDS HOSPITALS
DEPARTMENT OF MEDICAL PHYSICS

Applications are invited for the post of Physicist at a salary on the scale £625 by £25 to £700 a year, according to qualifications and experience. Candidates should have an honours degree in physics, but experience in radiation work is not essential. Duties will be concerned with problems of radiation protection and research in related fields. Facilities are available in the department for acquiring experience in the applications of physics to medicine and for preparing for a higher degree.

Applications (three copies), stating date of birth, qualifications and experience, together with the names of three referees, should reach the Registrar, the University, Leeds, 2 (from whom further particulars may be obtained), not later than September 1, 1958.

SENIOR SCIENTIFIC OFFICERS

required by

THE ATOMIC WEAPONS RESEARCH ESTABLISHMENT, ALDERMASTON, BERKSHIRE

for duty at Orfordness, Suffolk

Post 1. To be directly responsible to the Officer-in-Charge for the general direction and management of a team engaged on a programme of advanced development and complex field trials. Good organizing ability and interest in technical management are essential for this post.

The team is responsible for the design of airborne telemetry equipment and associated ground stations, the organizing and carrying out of complex field and flight trials and the evaluation of the results. There is ample scope for original design.

Post 2. To take charge of a section of the above team engaged in advanced electronic instrumentation development and to be responsible for the detailed technical direction of this work.

For both posts a first- or second-class honours degree or equivalent is required and several years' experience in electronics or communication equipment development including pulse and U.H.F. techniques. Experience in air borne radar and G.W. equipment development will be considered a distinct advantage.

Salary: £1,215 to £1,425 per annum.

Contributory Superannuation Scheme. A house, or assistance towards legal expenses on house purchase, will be available for married officers living beyond daily travelling distance.

Postcards for application forms to the Senior Recruitment Officer at A.W.R.E., Aldermaston, Berks. Please quote ref. 1969/34.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Senior Lecturer or Lecturer in Botany. Salary scales per annum: Senior Lecturer, £1,700 to £2,050; Lecturer, £900 to £1,650; initial salary and status according to qualifications and experience. Membership of F.S.S.U. and Children's allowance scheme. Candidates should have special qualifications in plant physiology, and preference will be given to persons with interests and research experience in biochemistry.

Applications should be sent not later than September 30, 1958, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

DIRECTOR

CAWTHRON INSTITUTE, NELSON, N.Z.

Applications for the above position are invited from those who are academically well qualified, of proven scientific leadership and administrative ability, to develop researches primarily into plant nutrition problems of horticulture and agriculture. Salary scale £2,000 to £2,250.

Details are obtainable from the Managing Secretary, Cawthron Institute Trust Board, Box 29, Nelson, N.Z., or the N.Z. High Commissioner, 415 Strand, London, with either of whom applications close on September 30, 1958.

COMMONWEALTH of AUSTRAL

AUSTRALIAN ATOMIC ENERGY
COMMISSION
CHEMISTRY SECTION. APPOINTMENT
SENIOR RESEARCH OFFICER OR
PRINCIPAL RESEARCH OFFICER (£A.2,06
£A.2,336 or ; £A.2,556/£A.2,996)

A vacancy exists for an experienced resea
chemist to take charge of a group within
Chemistry Section of the Commission's Resea
Establishment at Lucas Heights, Sydney.
position holds good prospects of promotion a
further responsibility. The Commission's resea
programme includes the study of two high te
perature reactor systems and of the reprocessi
of a range of nuclear fuels. A feature of the
search programme is the interest in berylliu
both as a moderator and fuel diluent. The n
chemical laboratories at Lucas Heights are of
very high standard of construction and are
cellently equipped for radiochemical work as w
as for more conventional instrumental and
organic studies. Irradiation facilities will
available in the Commission's recently comple
high-flux research reactor (H.I.F.A.R.). Qual
cations. Applicants should possess at least a fir
or second-class honours degree, and have had su
stantial research experience, preferably in the fie
of inorganic or physical chemistry. Radiochemi
experience would be an advantage. The salary
appointment will be dependent upon qualificatio
and experience. Conditions. Confirmation of
pointment carries with it Commonwealth Supera
nuation Fund or Commonwealth Provid
Account privileges. In the case of applicants fr
overseas, consideration will be given to a thr
year appointment. First-class fares and settling
allowances will be paid by the Commission.

Further information concerning the Commiss
may be obtained from the Commission's Liais
Officer in Australia House. Applications, givi
full name, date and place of birth, nationali
marital status, present position and salary, qua
fications, experience, particulars of any public
tions, the names and addresses of at least tw
referees, who may be contacted re technical
perience, and when available for duty, should
forwarded to the A.A.E.C. Liaison Offic
Australia House, Strand, London, W.C.2, n
later than Friday, September 19, 1958.

SIERRA LEONE

SYSTEMATIC BOTANIST/ECOLOGIST

To study grass weed problems of the inla
rice bolis and to advise on control measures;
study problems of low fertility and yields in are
being developed for mechanical rice cultivatio
Candidates must have an honours degree in bota
and at least two years' research experience pref
ably in ecology; or an honours degree or equiv
lent in agricultural science plus two years co
pleted postgraduate training in botany, preferab
with an ecological bias. Agricultural and tropic
experience would be an advantage. Age: N
over 35. Appointment is on (i) permanent a
pensionable terms with pensionable emolumen
in range £966 to £1,776 per annum (ii) perma
ent Research Branch terms, or (iii) on contrac
gratuity terms with emoluments in scale £1,039
£1,924 with a gratuity of £37 10s. for each co
pleted period of three months' satisfactory servi
payable on completion of engagement. Free pa
sages for officer, wife and up to two depende
children under nineteen years of age. Furnish
quarters, when available, at moderate rental. O
fit allowance £60 on first appointment. Taxati
at local rates.

Apply, giving brief particulars, to Director
Recruitment, Colonial Office, London, S.W.
quoting BCD.63/15/012.

NORTH OF SCOTLAND COLLEG OF AGRICULTURE

Applications are invited for the following sta
vacancy: Assistant Advisory Officer in Grasslar
Husbandry. Candidates should possess an honou
degree in agricultural botany or a B.Sc. pass d
gree in agriculture. Specialized postgraduate e
perience in Grassland Husbandry is desirable b
not essential. The duties will include investig
tional work. Salary scale, National (men), Gra
III, £835 to £1,320 per annum; Grade IVa, £6
to £825 per annum; Grade IVb, £595 to £825 p
annum. Entry to one of the above scales will
according to age, qualifications and experience a
the successful candidate must be prepared to ser
in any part of the College area. Superannuati
scheme.

Forms of application, which may be obtain
from the Secretary of the College, must be lodg
not later than September 20, 1958.

41½ Union Street,
Aberdeen.

RTH OF SCOTLAND COLLEGE OF AGRICULTURE

pplications are invited for the post of Assist- Lecturer in Bacteriology. Candidates must be luates and for a Grade III appointment should e had suitable postgraduate experience. The essful candidate will be required to take part he lecturing and advisory investigational work he Department. The appointment will be on of the following salary scales with entry rding to qualifications and experience: Grade (men), £835 to £1,320; (women), £788 to 51. Grade IVa (men), £615 to £825; men), £615 to £787. Grade IVb (men), £595 825; (women), £595 to £787. Superannuation me.

urther details and application forms may be ained from the undersigned, with whom appli- ons must be lodged not later than September 1958.

HUGH MUNRO,
Secretary.

1½ Union Street,
Aberdeen.

QUEEN MARY COLLEGE

(UNIVERSITY OF LONDON)

MILE END ROAD, E.1

NUCLEAR ENGINEERING LABORATORY

RESEARCH ASSISTANT

To help in developing equipment and to supervise the laboratories. Experience in a laboratory, adaptability and enthusiasm are more important than paper qualifications. Electronic and nucleonic experience desirable, but training in nucleonics will be given where necessary. Appointment according to ability, etc., on scale £800 by £35 to £1,000 per annum. Pension scheme. Five-day week. Four weeks annual leave.

Letters only to Professor Murgatroyd, stating age, details of experience and present work.

FEDERATION OF NIGERIA

NCIPAL FISHERIES RESEARCH OFFICER

o lead a small group of scientists and techni- ıs in either Sea Fisheries Research or Inland heries and Fish Culture Research. Candidates st have a good honours degree in zoology and siderable postgraduate experience in fisheries earch. Appointment on contract gratuity terms a salary of £2,082 per annum. Gratuity of 10s. for each completed period of three nths' service (including leave). Free passages on ointment and leave for officer, wife and chil- n up to the equivalent of four adult passages ll. Furnished quarters if available at moderate tal. Generous leave.

pply, giving brief particulars, to Director of ruitment, Colonial Office, London, S.W.1, ting BCD.65/14/03.

ITY OF LEICESTER MUSEUMS AND ART GALLERY

PPOINTMENT OF KEEPER OF BIOLOGY

pplications are invited for appointment to the t of Keeper of the Department of Biology in Leicester Museums. Candidates should norm- hold a degree in botany or zoology, or the ploma of the Museums' Association and should e considerable museum experience. The salary be within APT Grade III (£845 to £1,025 per ıum), and the successful candidate will be re- red to pass a medical examination.

pplications, giving full details of qualifications l experience, should reach the undersigned by tember 30, next, and further particulars are ilable on request. There is no entry form.

T. A. WALDEN,
Director.

Museum and Art Gallery,
New Walk, Leicester.

NIVERSITY OF MANCHESTER

pplications are invited from graduates in chem- y or biochemistry for the post of Research sistant in Chemistry in connection with a grant m the British Empire Cancer Campaign Com- tee for work on the chemistry of nucleotides. lary would be £350 per annum. The person pointed would be required to take up duties on tober 1, 1958.

pplications should be sent not later than Sep- ıber 13, 1958, to the Registrar, the University, nchester 13, from whom further particulars and ms of application may be obtained.

CENTRAL ELECTRICITY GENERATING BOARD

RESEARCH AND DEVELOPMENT DEPARTMENT

Applications are invited for the post of DIRECTOR OF DEVELOPMENT PROJECTS (ELECTRICAL) in the Research and Development Department of the Central Electricity Generating Board at Headquarters, London, S.E.1. The successful candidate will be responsible to the Chief Research and Development Officer for the economic assessment, initiation and headquarters supervision of development projects in the fields of electrical equipment, transmission and system control undertaken both at out-stations and at the Board's Laboratories.

This is a senior appointment requiring wide experience of research or project direction in the fields of physics or electrical engineering. Previous experience in the heavy electrical supply or manufacturing industries would be an advantage but is not essential.

Candidates should have a good honours degree in science or engineering, or equivalent qualification.

Salary will be on a scale within the range of £2,960 to £3,860 per annum according to the agreed duties and responsibilities of the post.

Letters of application, stating age, qualifications and experience, present position and salary, should be forwarded to S. S. Scott, Chief Personnel Officer, Buchanan House, 24-30 Holborn, London, E.C.1, by September 8. Please mark envelopes "Confidential"—Ref. N./225.

UNIVERSITY OF ABERDEEN and ROBERT GORDON'S COLLEGES

Applications are invited for the post of University Lecturer in Mechanical Engineering. Candidates should preferably have qualifications in applied thermodynamics. An interest in heat transfer apparatus, or in the special problems associated with the generation of heat and power from nuclear reactors, and some industrial or research experience would be an advantage. There are excellent facilities for research or advanced studies requiring appreciable quantities of steam or compressed air. The University Regulations permit members of the teaching staff to read for the degree of Ph.D. by research. Salary in range rising to £1,650, with membership of the F.S.S.U. and children's allowances. Initial salary according to qualifications and experience. University owned accommodation becomes available from time to time.

Further information may be obtained from the Secretary, the University, Aberdeen, with whom applications (20 copies), giving names of three referees, should be lodged not later than October 1, 1958. An applicant outside the British Isles may submit one copy of application.

COMMONWEALTH BUREAU OF HELMINTHOLOGY

THE WHITE HOUSE, 103 ST. PETER'S STREET, ST. ALBANS, HERTS

Scientific Assistant required for work in scientific information service involving abstracting and indexing. Good science degree, reading knowledge of two European languages (preferably other than French or German) and ability to write good English essential. Knowledge of helminthology an advantage. Salary scale £595 to £970 (bar) to £1,330 (bar) to £1,460. Age, qualifications and experience considered when fixing starting salary. Up to two increments for compulsory National Service and two extra increments on completing two years' satisfactory service if aged 32 and under. Superannuation according to F.S.S.U.

Applications, stating age, qualifications and experience, together with names of three referees, should be sent to the Director before September 30, 1958.

UNIVERSITY OF CAMBRIDGE

Applications are invited for an Assistant Director of Research in general surface chemistry and colloid science. Applications will close on October 10, 1958.

Details of duties, salary, etc., may be obtained from Dr. F. B. Kipping, University Chemical Laboratory, Lensfield Road, Cambridge.

LABORATORY TECHNICIAN AND Student Technician required to assist in the general work of the Physics Department. Salary, Technician £535 to £660, Student Technician up to £456, according to age, training and experience.—Apply, Secretary, St. Mary's Hospital Medical School, Paddington, W.2.

DEPARTMENT OF AGRICULTURE

TANGANYIKA

PLANT PATHOLOGIST

Required for field and laboratory work in the diagnosis and investigation of fungal and bacterial diseases of crop plants and the testing of control measures. Candidates, male, must have a good honours degree in agriculture or natural science with at least one year's postgraduate training in mycology and plant pathology. A knowledge of virus diseases is desirable. Appointment on contract/gratuity terms with emoluments in range £981 to £1,863 per annum. Gratuity of 13½ per cent of total substantive emoluments at satisfactory conclusion of service. Outfit allowance £45 if emoluments do not exceed £1,284 per annum on first appointment. Furnished quarters, when available, at moderate rental. Free passages on appointment and leave for officer, wife and dependent children under 18 years of age up to a maximum equivalent to three adult passages in all. Taxation at local rates.

Apply, giving brief particulars, to Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/8/08.

RADIO-ISOTOPES IN INDUSTRY AND RESEARCH

An Experimental Organic Chemist is required, initially at Harwell and later at the nearby Wantage Radiation Laboratories, for work on organic and physical-organic chemical problems in the application of radioisotopes in industry and research.

Appropriate H.N.C. "A" level G.C.E. subjects, or equivalent qualifications required. Experience of chromatography and methods used in determination of carbon 14 and/or tritium in organic materials desirable.

Salary: £420 to £855 or £990 to £1,215 according to age and experience.

Send postcard to the Group Recruitment Officer (1183/37), U.K.A.E.A., Atomic Energy Research Establishment, Didcot, Berks, for application form and details.

SOMERSET RIVER BOARD

ASSISTANT IN THE FISHERIES AND POLLUTION DEPARTMENT

Applications are invited for the above appointment on Salary Grade A.P.T. II (£725 to £845). Applicants should have some knowledge of fresh water biology and chemistry. Duties will include inspection of sewage works and trade waste treatment plants, river surveys and the examination of samples. It will be an advantage if the person appointed is able to drive a car, for which an allowance will be paid. The post is superannuated and subject to N.J.C. conditions.

Applications, stating age, qualifications and previous experience, must reach the undersigned by September 15, 1958.

E. L. KELTING, O.B.E., J.P., M.I.C.E.,
Chief Engineer.

The Watergate, West Quay.
Bridgwater, Somerset.

NEW SOUTH WALES DEPARTMENT OF PUBLIC HEALTH

SYDNEY, AUSTRALIA

Applications are invited for appointment to the position of Officer-in-Charge, Radiation Branch, Division of Industrial Hygiene. Salary £A.2,000 to £A.3,000 per annum. Commencing rate according to qualifications and experience. Applicants must possess a university degree in science or engineering, with majors in physics and/or mathematics, or other equivalent qualifications. Special experience in radiational work is essential. The successful applicant will be mainly concerned in the administration of the Radioactive Substances Act and Regulations thereunder and will be required to organize and administer a new Branch of the Department. He will be required to advise the Department in all matters pertaining to radioactive isotopes and irradiating apparatus in regard to which he must have thorough experience. Administrative experience is also desirable. First-class ship fares to Sydney of appointee and family will be paid. Successful applicant will be eligible, subject to passing a medical examination, to contribute to the State Superannuation Fund.

Four copies of applications (including the names of two referees) should be lodged with the Agent-General for New South Wales, 56 Strand, London, W.C.2, by October 7, 1958.

GOVERNMENT OF HONG KONG

Physicist required for Radiological Department to collaborate with Radiologists on treatment techniques, supervise radiological workshop, assist in maintenance and development of equipment, maintain radiation protection services and instruct students. Appointment on contract for three years but shorter period could be arranged if necessary. Emoluments include basic salary on scale from £1,035 to £1,897 10s. a year; expatriation pay from £210 to £281 10s. a year; and variable cost of living allowance, which on minimum of salary scale is £41 a year for single man; £175 a year for married man with no children; and £310 a year for married man with dependent children, boys under 18 and girls under 21 years. Commencing salary depends on experience. On satisfactory completion of service a gratuity is payable from £37 10s. to £62 10s. for each completed period of three months' service. Arrangements could be made for preservation of superannuation rights of candidate from National Health Service. Free passages for officer, wife and up to three children under 18. Pending quarters becoming available, hotel or hostel accommodation provided. Maximum charge for quarters, hotel or hostel accommodation one-seventh of basic salary. Income tax at local rates. Climate favourable. Educational facilities available. Candidates must possess honours B.Sc. degree in physics and have had at lease five years' post-qualification experience as hospital Physicist.

Application forms from Director of Recruitment, Colonial Office, London, S.W.1 (quoting BCD. 117/51/013).

UNIVERSITY COLLEGE OF RHODESIA AND NYASALAND

Applications are invited for Lectureship in Chemistry from candidates with interests in Physical and/or Inorganic Chemistry. Salary scales: Assistant Lecturer, £1,050 by £50 to £1,200 per annum, Lecturer (Grade II), £1,200 by £50 to £1,450 per annum (Grade I) £1,450 by £50 to £1,750 per annum, entry point determined by qualifications and experience. Superannuation scheme. Passages to Salisbury for appointee, wife and dependent children on appointment with allowance for transport of effects. Unfurnished accommodation at rent of up to 15 per cent of salary. Assistance given for triennial leave overseas.

Detailed applications (six copies), naming three referees, by October 10, 1958, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

GUIDED WEAPONS. PHYSICISTS AND ENgineers required by Ministry of Supply at Royal Aircraft Establishment, Armament Research and Development Establishment and Royal Radar Establishment, for research on guided weapons (including ballistic missile) and supervision of development in industry. First- or second-class honours degree or equivalent required for Scientific Officer (£595 to £1,050) and three years' postgraduate experience in addition for Senior Scientific Officer (£1,130 to £1,330). Women's rates the same by 1961. Superannuation under F.S.S.U. Opportunity for those under 32 to compete for established posts.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1 (quote A.291/8A).

ROYAL NAVAL SCIENTIFIC SERVICE REquires Senior Scientific Officers and Scientific Officers for Establishments in London area, Baldock, Portsmouth, Portland, Poole, Greenock and Rosyth. Main requirements are about 25 vacancies for Physicists, Electronic Engineers and Mathematicians in areas specified. The following particular vacancies also exist: Mechanical Engineer for work on gas turbine problems in the London area. Mechanical Engineers for work on design and development of U/W devices in Portland area. Metallurgists for Rosyth and Poole. Chemists (Physical and Inorganic) for Poole area, Baldock and London. Candidates must normally be natural born British subjects of natural born British parents, with at least first- or second-class honours degrees or equivalent high professional attainments. Senior Scientific Officers must have had at least three years' postgraduate experience and be not less than 26 years of age. Salaries (men): Senior Scientific Officer, £1,190 to £1,410; Scientific Officer, £635 to £1,110 (London)—somewhat lower in provinces. Appointments unestablished (with F.S.S.U. benefits), but opportunities may occur for those between the ages of 21 and 32 to compete for established posts.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A98/8A.

ROYAL PERTH HOSPITAL
WESTERN AUSTRALIA

require a

SENIOR TECHNICIAN (CHEMIST)

for routine chemical pathology, special investigations and research, in the Biochemistry Department at this hospital. Qualifications: Degree or equivalent in chemistry or biochemistry, with experience in clinical or research biochemistry. Salary: According to qualifications and experience, but in the range of: males, £A.1,420 to £A.1,465 to £A.1,510 to £A.1,555 to £A.1,600 per annum; females, £A.1,075 to £A.1,115 to £A.1,155 to £A.1,195 to £A.1,235 per annum.

In addition to all relevant personal details, applications must include particulars of experience and qualifications, the names of two referees, and should be addressed to the undersigned, not later than September 30, 1958.

JOSEPH GRIFFITH,
Administrator.

UNIVERSITY OF LEEDS
DEPARTMENT OF MECHANICAL ENGINEERING

Applications are invited for appointment to the post of Assistant Lecturer or Lecturer in the Department of Mechanical Engineering at a salary within the range £700 to £850 a year for an Assistant Lecturer or on the scale £900 by £50 to £1,350 (efficiency bar) by £75 to £1,650, according to age, qualifications and experience. The person appointed would be expected to work in the general field of mechanical engineering but to take particular interest in control engineering. Knowledge of the aspects of control engineering which are related to production engineering would be useful. Previous teaching experience is not necessary but industrial experience is essential.

Applications (three copies), stating date of birth, qualifications, and experience, together with the names of three referees, should reach the Registrar, the University, Leeds, 2 (from whom further particulars may be obtained), not later than September 30, 1958.

CENTRAL ELECTRICITY GENERATING BOARD
METALLURGIST—RESEARCH LABORATORIES

METALLURGIST required at RESEARCH LABORATORIES, Leatherhead, Surrey, to assist in investigating unusual problems in the creep of metals used in nuclear power generation. Candidates should be L.I.M. or hold the H.N.C. in metallurgy or physics. Experience in conventional creep testing will be a recommendation, but applicants without experience in this field will be considered. Salary will be within scales £820 to £995 per annum or £550 to £725 per annum, according to qualifications and experience.

Applications, stating age, qualifications, experience and present position and salary, should be forwarded to I. G. Ellis, Personnel Officer, 24-30 Holborn, London, E.C.1, by September 12. Please mark envelopes "Confidential." Ref. N./244.

SENIOR SCIENTIFIC AND SCIENTIFIC Officers, required at Government Communications Headquarters, Cheltenham, for telecommunications and electronic research in following fields: V.H.F. receiver design and microwave techniques; propagation trials; applications of semi-conducting devices; high speed electronic switching; data storage and handling; computer programming, and operational research. Candidates must normally be natural born British subjects of natural born British parents. First- or second-class honours degree in physics, mathematics or engineering or equivalent, at least three years' postgraduate experience for Senior Scientific Officer. Salaries for men (provincial rates) Senior Scientific Officer, £1,130 to £1,330; Scientific Officer, £595 to £1,050 (according to age and qualifications). Appointments unestablished but opportunities to compete for established posts.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A147/8A.

AGRICULTURAL RESEARCH COUNCIL invite applications from persons qualified either in plant physiology or plant biochemistry to work on plant growth substances in their plant growth substance and systemic fungicide Unit at Wye College, near Ashford, Kent, under the direction of Professor R. L. Wain. Appointment in Scientific Officer (£595 to £1,080) or Senior Scientific Officer (£1,130 to £1,370) grade according to age and experience. Superannuation under F.S.S.U.—Applications, with copies of two recent testimonials, and names of three referees, to the Director of the Unit not later than September 30, 1958.

NEW SOUTH WALES UNIVERSI OF TECHNOLOGY
SYDNEY, AUSTRALIA
VACANCIES FOR SENIOR LECTURERS LECTURERS IN THE SCHOOL OF HUMANITIES AND SOCIAL SCIENCES

The University invites applications for appo ment to academic vacancies in the School Humanities and Social Sciences. Salary, Ser Lecturers: £A.2,211 range £A.2,561 per ann Lecturers: £A.1,511 range £A.2,111 per ann Commencing salary according to qualifications experience. Applicants for Lectureship m possess a degree preferably with honours, equivalent qualifications. For appointment Senior Lecturer an honours degree is essential.

Senior Lecturer/Lecturer in Sociology: Ap cants to be qualified in Sociology or So Anthropology, or in some related field that cludes substantial work in sociological theory method.

Lecturer in Philosophy: Applicants to be qu fied in Philosophy and qualifications in one more of the sciences and ability to lecture History and Philosophy of Science will be advantage.

Lecturer in Government: Applicants to be qu fied in political science or some allied study.

Appointees will be eligible, subject to passin medical examination, to contribute to the St Superannuation Fund. First-class ship fares Sydney of successful applicants and their fami will be paid.

Applications (including the names of t referees) should be lodged with the Agent-Gene for New South Wales, 56 Strand, London, W.C and a copy forwarded by airmail to the Burs New South Wales University of Technology, I 1, Post Office, Kensington, New South Wa Australia, before September 20, 1958.

UNIVERSITY OF SHEFFIELD

Applications are invited for a post of Jun Research Fellow in Geography to begin duties October 1, 1958. Salary £550 per annum. T appointment will be for one year in the first stance, but will be renewable.

Applications (three copies), with the names a addresses of two referees, should reach the Re trar, from whom further particulars may be tained, by September 13, 1958.

NORTHERN POLYTECHNIC
HOLLOWAY, LONDON, N.7

Applications are invited from Honours Gra ates in Physics for appointment as RESEAR ASSISTANTS for problems concerned with f particle techniques, gas discharges, spectrosc and electronics. Candidates appointed can qua by research for the Ph.D. degree. Rate of pay approximately £480 per annum.

Further particulars and form of application tainable from the Clerk to the Governors.

BRITISH GUIANA
AGRICULTURAL SUPERINTENDENTS

Duties mainly concerned with agricultural tension work and management of demonstrat farms and stations. Candidates must have a u versity degree in agriculture or horticulture and least two years' suitable postgraduate training experience. Appointment on probation to permanent and pensionable establishment w salary in scale £770 to £1,400 per annum or contract/gratuity terms if preferred. Gratuity the rate of 22¼ per cent of salary. Free passa on appointment for officer, wife and children exceeding five persons in all. Assisted leave p sages. Unfurnished quarters at moderate rental

Apply, giving brief particulars, to Director Recruitment, Colonial Office, London, S.W quoting BCD.63/30/011.

SCOTTISH HORTICULTURAL RESEARCH INSTITUTE

Applications are invited for two posts as Sci tific Officer: (1) Soil Microbiologist (Mycologi for work on isolation and identification of possi vectors of soil-borne viruses. (2) Entomologi Virologist for work on problems of virus transm sion. Salary scale £595 to £1,050. Placi F.S.S.U. Candidates should have a good hono degree in appropriate subjects.

Applications, giving age, full details of edu tion, qualifications, experience and naming th referees, will be considered from home candida and overseas candidates due to return to t country in the reasonably near future, and sho reach the Secretary, Mylnefield, Invergowrie, Dundee, not later than October 4. There are application forms.

The Science of High Explosives

by MELVIN A. COOK

Professor of Metallurgy, Director, Explosives Research Group, University of Utah.

A REINHOLD BOOK

This new American Chemical Society monograph describes detonation processes and related phenomena with theoretical interpretations and many illustrations, and includes much material which has never before been published. Initiation, wave structure, propagation, the nature and rates of chemical reactions of detonations, ionization, radiations, shock and blast waves, and damage resulting from detonation are all critically discussed and evaluated.

Physical Chemistry of High Polymers

by MAURICE L. HUGGINS

Research Associate, Kodak Research Laboratories, Rochester, N.Y.

A JOHN WILEY BOOK

This work covers the whole subject, extending the concepts of classical physical chemistry to systems containing large molecules. The molecular structures of synthetic and natural high polymers (including proteins) are described in detail. The book contains the results of much recent work in the field, including the author's previously unpublished theory of the dependence of the thermodynamic properties of polymer solutions on the sizes, shapes, and structures of the component molecules.

PRECISION INSTRUMENTS

Refractometers for Industry and Research

Our well-known standard Abbe type refractometer has a refractive index scale on glass and is read by transmitted light, thus leading to greater convenience in taking measurements and a higher degree of accuracy.

The instrument as illustrated is supplied with degree scale arc and micrometer screw reading directly to 10 seconds, corresponding to a refractive index accuracy within 0.00005. Conversion tables for use with sodium light are supplied.

Full particulars sent on application.

We shall be pleased to demonstrate these instruments and give any advice within our power, if you will call at our Works.

SCIENTIFIC RESOURCES AND ATOMIC ENERGY

THE fourth annual report of the United Kingdom Atomic Energy Authority*, covering the year ended March 31, 1958, records substantial progress in the Authority's commitments in regard to defence, research and development on the civil applications of nuclear energy, consultancy service to the electricity authorities and collaboration with industry in the nuclear power programme. As was the case with previous reports, it is still impossible to assess the magnitude of the Authority's demand upon the resources of Great Britain in either man-power or materials. The operating account continues to be withheld from publication in the interest of national security, and the balance sheet merely records an item of £2,398,971 for research and development expenditure in aid of design (as against £2,691,341 the previous year). However reasonable that particular course may be, an assessment of the nation's research and development effort as a whole is becoming increasingly necessary, and it would seem from the report that defence considerations are a serious obstacle.

Nevertheless, the report provides a convenient and authoritative review of the Authority's many-sided contribution to Britain's economic development, the value of which is not seriously diminished by the fact that security considerations have been allowed to impose secrecy a little beyond what was essential and thereby hindered discussion of those features of the year's work which have excited most interest and aroused most concern. The time factor may account for the absence of the information which would enable some judgment to be made as to how far the Authority has been able to implement the recommendations of the Fleck reports and eliminate the fundamental weakness which the Windscale accident laid bare, namely, the spreading of the strictly limited amount of skilled staff ever more thinly over a rapidly expanding organization. As regards the future, industrial application of nuclear energy secrecy has not prevented the publication of an outline of the position. Nevertheless, it is important not merely that secrecy should be kept to the minimum but also that there should be general confidence that this is being done.

On this last point the present report adds nothing to the statement of policy given in the previous annual report, and it should be obvious that in the aggregate the functions which the Authority has assumed in regard to education and in its relations with industry must have a considerable effect in disseminating information about nuclear energy, quite apart from publication policy proper and the considerable programme of exhibitions described in this report. The publication policy, including the numerous papers and addresses contributed by the Authority's members and officers, which numbered more than 1,400 during the year, has made much of the information on research and development described in this report familiar to readers of *Nature*, so that recapitulation is unnecessary. It may suffice to note that the uranium situation has eased and that the Authority's interest in helium as a heat-transfer medium has led to drilling at a site in Tanganyika where unusually high concentrations have been reported. The Windscale accident, however, has demonstrated convincingly the value and importance of effective public relations. Indeed, it is perhaps only with that as background that the fullest benefits to all concerned arise from the contacts with industry described in the report under "Relations with Industry".

The Authority can only accommodate a limited number of attached staff, but the hundred or so scientists and engineers from British industry attached to the Authority's establishments at the end of the year are promoting a valuable interchange of ideas between the Authority and industry, acquiring experience for themselves which is not obtainable elsewhere and reinforcing the Authority's own technical resources ; no less important, they supplement the contribution to technological education which is made by the Harwell Reactor School and the Calder Operations School, and the five conferences held at Harwell during the year. The Reactor School extended its scope considerably, and the first six weeks of the standard course, which has been increased from fourteen to sixteen weeks, are now held at the Birmingham College of Technology, Bradford Institute of Technology, or Salford Royal Technical College. These courses and the Senior Technical Executive Courses and other courses during the year were attended by 378 British and 120 overseas students, while 32 British and 41 overseas students attended the Calder Operations School, which as more information on the operation of the Calder Hall reactors becomes available is increasingly able to provide a basic course of instruction for those who will ultimately operate similar types of reactor.

The Authority's staff again increased, from 27,290 on April 1, 1957, to 30,341 on March 31, 1958, the industrial staff increasing from 14,660 to 15,860, and reference may be appropriately made here to the Authority's arrangements for training its own staff. These continue to be developed in the light both of the White Paper on Technical Education and of the report of the Carr Committee. In particular, the Authority, which recruited 18 student apprentices and 150 craft apprentices during the year, is reviewing its arrangements in the light of the Carr report, in order to take advantage of the larger number leaving school during the next few years. Training schemes within the Authority, including full-time courses in laboratory techniques for junior staff, have been further expanded, and full-time degree courses in universities and sandwich courses at technical colleges continue to be awarded both to selected student apprentices and to selected members of the junior staff. Courses and management conferences for senior staff remain a developing feature of the Authority's training arrangements.

---

* United Kingdom Atomic Energy Authority. Fourth Annual Report for the period 1st April 1957–31st March 1958. Pp. vi+68. (London: H.M. Stationery Office, 1958.) 4*s*. 6*d*. net.

This contribution to technological education needs to be kept in mind in considering the demands of the Authority under Britain's man-power resources, while the Authority's internal training programme has a decisive influence in removing what is probably the most serious limitation upon its plans to-day. It is apparent from this report, as from those of the Fleck Committees, how heavy is the responsibility that rests on the works manager and his team at the plant. It is no less apparent that the Authority is seriously short of first-class talent for promotion. Following the reports of the Fleck Committees, the Industrial Group has embarked on an intensive recruitment campaign to bring existing complements up to strength and to fill new posts resulting from the Committees' recommendations. Some of these posts have already been filled by promoting suitably qualified members of the Authority's staff, but the report admits a substantial margin of vacancies to be filled from external sources.

Now while the report quite rightly points out that it is still too early to assess the results of this recruitment campaign, it is fair to comment that there is unlikely ever to be an excess of staff of the high calibre and breadth of experience required for the most senior posts, and the Authority must look in the main for more managers from within its own ranks, and in fact from its own scientists and technologists, who alone are likely to possess the necessary technical qualifications or experience. Moreover, the shortage is not limited to the Industrial Group. There are probably more posts in the higher administration than there are trained men to fill them. The list of senior staff given in this report indicates that the place of deputy director of Aldermaston has not been filled since the former deputy director, Sir William Cook, took Sir Christopher Hinton's place as member for engineering and production.

It is clear enough from this report that the Authority is doing its utmost to increase its staff and to find the men required for the additional posts recommended by the Fleck Committees, though the setting up of the Committee with Sir Douglas Veale as chairman to advise on the training and provision of specialist health and safety staff for the Authority and the nation as a whole, represent in the first instance an increased demand on trained man-power. It will be remembered, however, that the Committee which considered the organization of certain parts of the Authority contemplated deliberate curtailment, if only temporarily, of some of the Authority's activities to enable the Authority to recruit sufficient staff of the high quality required, or to strengthen the technical staff at the levels indicated in the report. It is not apparent from the present report how far the Authority has considered such a reduction in its activities, in order that its programme would match the staff it has available.

Admittedly, there are possibilities that the responsibilities of the Authority may be covered by developments already in train. The new centre of nuclear studies should relieve the Authority of some of the purely physical research, and the universities should be able to do the same as the new equipment now being constructed comes into use. It is reasonable to expect that the relations with industry now being developed could do the same in the development of nuclear power for peaceful purposes; but if the possibilities are to materialize, a deliberate policy of shedding responsibility on the part of the Authority may be required. Some hint that this is being considered might well have been expected in the report, though it is noted that some research in controlled thermonuclear problems is also proceeding in the universities and in the laboratory of Associated Electrical Industries at Aldermaston.

So far as the actual development of nuclear energy is concerned, the report shows that the commissioning of the fast breeder reactor at Dounreay is regarded as less urgent than two or three years ago. The diversion of operating staff necessitated by the Windscale accident has extended the commissioning period, and the fast reactor will not become critical for several months after April 1, 1958, the original date. At Dounreay the Materials Testing Reactor is regarded as a much more urgent requirement, and Sir William Cook has stated that it will be three years before the place of the fast reactor in the hierarchy of industrial reactors can be assessed. Use of plutonium as fuel for fast reactors, in which it is most advantageous, will not be attempted for some time.

Meanwhile, it appears that the Authority's main hopes rest on a further development of the Calder Hall type of reactor, and its primary objective during the 1960's will be to realize the maximum potentialities of the gas-cooled, graphite-moderated reactor system. No further work is to be undertaken on the sodium-cooled graphite-moderated reactor system for the present. Technological and scientific knowledge, it is believed, are growing too rapidly to allow formulation of a firm long-term programme; but the present intention is to use beryllium-clad uranium oxide as fuel, although the reactor will be designed so as to allow alternative forms of high-temperature fuel to be tested on a large scale. The lower capital cost of this advanced gas-cooled reactor will offset the falling load factor which inevitably occurs as nuclear power supplies an increasing proportion of the nation's electricity; and it is possible that a scaled-down version of this reactor system might be suitable for merchant ship propulsion. The Authority is continuing to study the development of alternative systems, however, and by the 1970's work on the fast breeder system might have reached a stage at which commercial power stations can be built. The high-temperature gas-cooled reactor is also receiving detailed consideration as a potential reactor for nuclear power stations; but the prospects of commercial exploitation of energy from controlled thermonuclear reactions are for the future, and it is as yet impossible to suggest when a contribution to power supplies from this source can be expected.

This recent announcement by the Minister of Supply about plutonium adds interest and importance to the accounts of the processing plants in the Atomic Energy Authority's report, and the decision may well require greater effort at Capenhurst and elsewhere. Moreover, the prospects opened up by the successful navigation beneath the North Pole of *Nautilus* since the report was written might indeed lead to higher priority being given to the work on marine propulsion and possibly justify greater effort in that field. The Authority is already making an intensive study of the engineering design of a merchant ship, which should be complete in about a year; but even if this shows that a merchant ship powered by a nuclear reactor is likely to be economic, such a vessel could scarcely be commissioned before 1963 or 1964.

Studies so far made indicate that a scaled-down version of the Calder Hall type of reactor would be unsuitable for marine propulsion, except for very large vessels, and at present the advanced gas-cooled graphite-moderated reactor is being considered for this purpose as well as a gas-cooled reactor moderated with heavy water, while the organic-liquid moderated reactor system also offers possibilities of a compact system in which the containing vessel need not be capable of withstanding high pressure. Apart from any impetus which may be derived from the achievement of *Nautilus*—and for submarine propulsion the pressurized-water reactor system is particularly suitable—the reactors for marine propulsion, particularly the heavy-water moderated reactor, appear to have potentialities for small land-based power stations and hence for export purposes.

Considerable development effort will be necessary before economic reactors for these purposes can be produced, and the report points out that the diversion of scarce resources, technological skill and development effort cannot be justified until, for example, the prospect is seen of getting to sea a ship that is economic—or well on the road to that end. Nevertheless, the picture may have changed substantially since the report was written and planning permission for construction of the prototypes already granted. What matters, however, is the relevance of that effort not simply to the Authority's own staff and resources but also its relation to the nation's research effort as a whole. The main lesson which the Windscale accident has taught is that the Atomic Energy Authority must adjust its programme to the man-power which it can actually command; hence it is no less essential that the man-power which Britain can put at the disposal of the Authority should be determined with reference to other national needs.

The demonstration of the practicability of submarine polar navigation emphasizes the importance and urgency of one phase of the Authority's work; at the same time, it raises the question whether, when the fullest possible use is made of Anglo-American co-operation and the information which the United States can put at the disposal of Britain, it is not desirable that Britain should put some effort into research and development of the system of inertial navigation. In addition, however, while the Minister of Supply has recently told the House of Commons that the Ministry has been in constant touch with the Royal Society about the possibility of launching an Earth satellite, following his visit to the Woomera rocket range on August 7, Mr. Aubrey Jones has referred to the possibility of Britain undertaking a satellite programme using the Bluestreak long-range ballistic missile and the Black Knight high-altitude research rocket. Mr. Jones admitted that it would be unwise to make such an expensive diversion of effort unless it was warranted by the information that satellites would yield, and he asked the sensible question whether Britain really needs missiles of inter-continental range.

The further question should be asked whether the diversion of effort into the development of an Earth satellite could be justified. The Minister's remarks suggest that serious consideration is being given to a project which has been advocated, largely on grounds of prestige, for almost a year; but Britain can ill afford the diversion of scientific and technological resources, in equipment and materials as well as of man-power and finance, unless there are convincing reasons which would outweigh, for example, any consequent curtailment of nuclear development or research. To launch into such an undertaking except for the most convincing reasons of public interest could be wasteful extravagance.

Less concern might well be entertained over the prospect if there were not so little evidence that, both within the Authority itself and outside it, Britain's effort in the field of nuclear energy is being considered and planned in relation to the total resources of the country and the considered needs of other fields of scientific and technological inquiry and development. There is, on the contrary, much evidence of continuing piecemeal approach and action, and of this the Atomic Energy Authority's report provides further evidence in its silence about the siting of the future nuclear power stations. That is, of course, now the responsibility of the Central Electricity Generating Board; but the Authority might reasonably have been expected to comment on the working life of the nuclear power station. The realization that this is now expected to be no more than twenty or thirty years has deeply disturbed public opinion over the decision of the Minister of Power and the Minister for Welsh Affairs to approve the siting of a station at Trawsfynydd in the Snowdonia National Park and makes the haphazard and piecemeal siting of such stations intolerable.

Suitable sites for large nuclear power stations in Britain are not easy to find; but if such a power station is to be sited in a national park in a country so developed as Britain, there should be irrefutable evidence that the national interest will be grievously and irreparably damaged if the proposal is refused.

Moreover, the obstacles to placing the power station and its transmission lines underground should be made public; and if cost is the sole obstacle, that should be precisely known.

It is the failure to face the implications of a considered policy and to recognize that Britain's resources in finance, man-power, materials, equipment and amenity are limited and can be stretched too far, which is responsible for the concern over Government policy in regard to technological development. The Atomic Energy Authority's report supplies no evidence that the period of piecemeal action is ended. Accordingly it is necessary to reiterate that implementation by the Authority itself of the recommendations of the Fleck Committees alone will not suffice. If Britain is to reap the full benefits of the varied activities of the Authority—benefits which extend not merely into the medical field but increasingly, with the opening of the Wantage Radiation Laboratory, into such fields as industrial polymerization and the improvement of synthetic fibres and reduction of the immense loss of stored products through insect pests—it is not enough to bring the Authority's own programme and activities into balance with its resources in trained man-power. It is no less essential that the resources made available to the Authority are themselves in harmony with the other numerous and conflicting demands on the nation's limited resources of finance, materials, equipment and trained man-power.

MECHANICAL TRANSLATION

Mechanical Resolution of Linguistic Problems

By Dr. Andrew D. Booth, L. Brandwood, and Dr. J. P. Cleave. Pp. vii+306. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1958.) 50*s.*; 9.50 dollars.

Programming for an Automatic Digital Calculator

By Dr. Kathleen H. V. Booth. Pp. vii+238. (London: Butterworths Scientific Publications; New York: Adademic Press, Inc., 1958.) 42*s.*; 9.80 dollars.

THE second of these books is a companion volume to the former, and is essentially a programmers' handbook to the APEXC, the magnetic drum computer at Birkbeck College, London, which has been used for many of the experiments on language translation described by Dr. Booth and his colleagues. The book is not only a companion volume, of course, but also contains much information about how the more familiar processes of numerical analysis are programmed for a machine of this type. Thus, for example, the topics covered include input and output, division and square root, evaluation of functions by power series, floating point operations, solution of simultaneous linear equations, evaluation of latent roots, and finally, 'post mortem' checking programmes.

The first book deals primarily with language translation, although by way of introduction the authors include as "linguistic problems" various aspects of the investigation of literary style, such as lexicography, and the analysis of rhythm and syntax. For all these purposes the text has to be encoded and punched on teleprint tape (or other input medium) for scanning by the machine. The first four chapters describe how the machine can read and interpret information presented in this form. The question of stylistic analysis is discussed in relation to the problem of determining the chronological sequence in which Plato wrote his works.

In Chapters 5 and 6, there is a very good account of the general aspects of language translation, and the programming techniques used to overcome some of the difficulties. Thus it would appear that the first task is to construct a stem-ending dictionary so as to reduce the vocabulary to a manageable size, otherwise if all the inflected forms of every word were given the dictionary would grow to unmanageable proportions. The dictionary look-up process matches each word of the input text with a dictionary of 'stems'. When the stem has been located it is removed from the word and the remainder looked up in a dictionary of "endings". The two pieces of information derived from these dictionaries together give the equivalent of the input word. Naturally, variations of this procedure are necessary for a language in which inflexions are made by means of prefixes. Refinements of the matching procedure are also necessary in the case where the stem and ending are connected by redundant joining letters (as an example the authors consider some regular French verbs). To operate a dictionary in this case necessitates left-to-right matching to select from the stem dictionary the longest entry which is part of the input word. Once the stem has been removed, right-to-left matching is used to locate the ending. The remaining letters can then be discarded. A similar technique is used to deal with compound words, which are such a common feature of technical literature.

The dictionary search procedure which the authors recommend for an automatic computer is essentially the same as one would normally use, that is to say one opens the book (roughly) in the middle, and then proceeds to narrow down the entry in question by a partitioning process. By employing a binary subdivision process for this purpose a dictionary of N entries can be searched in approximately $\log_2 N$ matchings.

Other problems considered in Chapter 6 are connected with word order, idioms, multiple meaning and ambiguity. The problem of word order, for example, is to translate "équation différentielle est" into "differential equation is". A fairly simple procedure suffices in this case, to invert the order of adjective and noun, but in translating from highly inflected languages, where the relations between words is governed almost entirely by endings, more elaborate devices are necessary to ensure the appropriate rearrangement in the English equivalent.

Chapter 7 is concerned with the mechanical transcription of Braille, a problem which at first sight appears to have little to do with language translation. The difficulty, however, lies in the rules for forming *contractions*, where parts of words, such as 'con' and 'ion', are abbreviated to a single Braille symbol. While clear enough in their intention, they are not immediately suitable for programming because they cannot always be expressed formally in terms of the sentence structure, but depend very much on the context of the symbols the contraction of which is to be made; for example, they should not overlap well-defined syllable divisions. The authors conclude that the machine production of Braille text is not an economic possibility at present, in view of the large amount of voluntary effort available.

Chapter 8 describes an experimental scheme for translating from French into English devised for APEXC. For reasons of storage space the scheme was limited to a dictionary of 250 words and their English equivalents, but the programme was sufficiently comprehensive to perform certain operations of syntactical nature, and to recognize the masculine and feminine, singular and plural forms of nouns and adjectives, and also all parts of the verb except the first person imperative and the subjunctive mood.

The last part of the book is devoted to the translation of German, a subject which, unfortunately, the reviewer is not able to comment on.

The authors conclude by considering the technical details of a machine designed specially for translating. The principal feature of such a machine, of course, is a large high-speed store. Various special orders are recommended to facilitate the dictionary look-up process, and at the same time orders such as multiplication can be dropped. The authors suggest that such a machine could be built for between £50,000 and £100,000 but are rather sceptical of obtaining financial support on this scale. However, their proposed instruction code for a linguistic machine is not so very special, and it would scarcely seem worth while to build a machine on this scale which would exclude it from doing tasks other than language translation. The authors' best hope, therefore, lies in the super-high-speed computers at present under development, such as Stretch or Larc.

R. A. Brooker

WORK ON FUSED SALTS

Soviet Research in Fused Salts (1949–1955)

(Chemistry Collection, No. 1.) General. Pp. 28. Structure and Properties: Ternary Reciprocal. Pp. 200. Structure and Properties: Quaternary Systems; Quaternary Reciprocal Systems. Pp. 98. Structure and Properties: Preparation; Iodine Systems. Pp. 156. Structure and Properties: Binary Systems: Ternary Systems. Pp. 284. Slags and Mattes. Pp. 39. Electrochemistry. Pp. 54. Thermodynamics. Pp. 58. Translated from the Russian. (New York: Consultants Bureau, Inc.) n.p.

Interest in the structure and properties of fused salts has been growing with noteworthy vigour in the past few years in various countries. From the fundamental point of view, molten salts constitute a distinct class of fluids, with an extensive range of temperatures over which the liquid state may be stable, with high heats of vaporization, and with quasi-crystalline structures in which the tendency for an ion of one sign to be preferentially surrounded by ions of opposite sign imposes an additional element of order, compared with other liquids. Despite the technical difficulties to be overcome, these characteristic properties have stimulated various basic researches on the transport and thermodynamic properties of ionic melts, and on melting mechanisms of ionic crystals.

The very great importance of fused salts in electrometallurgy, particularly of the more electropositive or reactive cation-forming elements, has for many years prompted applied research the bulk of which greatly exceeds the body of fundamental studies available in published literature. Much of this research is somewhat empirical. In addition to their interest for electro-metallurgy, fused salts have many analogies with fused silicates used as slags in bulk production of various metals. Their physical properties for applications as heat transfer fluids and bath fluids are also attracting increasing attention. All these considerations make any additions to published research, especially on the fundamental properties of fused salts, particularly welcome at the present time. Unfortunately, for many Western scientists researches published in Russian must still be regarded as not freely available until translations become accessible. The appearance of this collection prepared by the Consultants Bureau Inc. can therefore be described as very timely.

Translations necessarily suffer from certain defects in reproducing new knowledge. For example, the present collection includes nearly one hundred papers on melting and phase relationships for binary, ternary and quaternary mixtures of salts. The curves by means of which much of this information is recorded suffer in precision through the process of reproduction; such records may not be sufficiently accurate or clear for some purposes. However, it is very useful to know even the approximate shape of the diagrams in many cases.

In addition to a great bulk of work on phase diagrams, a limited number of the papers included give calculations on activity coefficients from electromotive force data, on the surface tension, density, viscosity and electrical conductivities of melts, on corrosion of metals by melts, and on slags.

Though discussions of basic theoretical considerations are included in some of the papers, the inspiration of much of this work appears to be technological. It constitutes an extensive body of factual knowledge about fused salts which should prove useful to those who do not have access to the original publications.

SOCIAL MEDICINE

The Teaching of Hygiene and Public Health in Europe

A Review of Trends in Undergraduate and Postgraduate Education in Nineteen Countries. By Prof. F. Grundy and Prof. J. M. Mackintosh. (World Health Organization: Monograph Series, No. 34.) Pp. 254. (Geneva: World Health Organization; London: H.M. Stationery Office, 1957.) 15 Swiss francs; 25*s.*; 5 dollars.

During the past hundred years scientific methods have been applied widely in medical research and practice; in the same period the health of the population of the Western world has improved. But the improved health owes less to advances in medical science than to changes in the external environment, and a favourable trend in the standard of living. We are healthier than our ancestors not because of what happens when we are ill but because we do not become ill; and we do not become ill not because of specific protective therapy but because we live in a healthier environment. In its preoccupation with the minutiae of diagnosis and the pathogenesis of disease, medicine is in danger of neglecting what has hitherto proved its most powerful resource—the manipulation of the external environment—and of failing, when it can do no more, "au moins à nous mener à la fin de la vie par un chemin agréable".

These are among the considerations which have led to an attempt to improve the teaching of preventive and social medicine, and the report prepared for the World Health Organization by Prof. F. Grundy and Prof. J. M. Mackintosh provides a valuable account of the instruction given in the medical schools of Europe. They describe briefly the curriculum in different countries, and interpret the trends in undergraduate and postgraduate teaching. Perhaps the most obvious conclusion suggested by their report is that there are still wide differences of opinion about what is needed. In Oslo and Amsterdam it is considered desirable to have two separate departments of hygiene and social medicine, and this pattern is soon to be extended to Sweden. In London no medical school has a chair of social medicine, and instruction is entrusted to part-time teachers or to other departments.

There are equally wide differences of opinion about the interpretation of the subject itself, for while the concept of social medicine evidently means a great deal to many people, it does not always mean the same thing. To the original core of traditional public health teaching have been added a number of other subjects—medical administration, medical statistics, human genetics, demography, social biology etc.—some of which have little more in common than the facts that they are obviously important, and either are not taught or are inadequately taught by any other department. Indeed social medicine has come to be identified with almost any medical theme which is statistical in its method or social in its implications; it is scarcely surprising that the syllabus which has resulted is overweighted and lacks coherence. As Grundy and Mackintosh recognize, if the subject is to make its full impact on medical education there will have to be some contraction of its ill-defined terms of reference, with, one would add, a synthesis of the material which remains.

THOMAS MCKEOWN

POLES, NORTH AND SOUTH

Arctic and Antarctic

A Prospect of the Polar Regions. By Colin Bertram. New edition, entirely revised. Pp. ix+123+13 plates. (Cambridge: W. Heffer and Sons, Ltd., 1958.) 21*s*. net.

NINETEEN years ago, in the preface to the first edition to this book, the author wrote, "The idea then came to me that it might be worth while attempting, not to record the narrative of an expedition, but to state some principles, physical, physiological and psychological, which govern the life of men in polar lands, presenting them in a way which might be of interest to others than specialists. When the attempt was made to follow out this plan, it soon became obvious that the underlying principles of dietary, housing and transport could be far more attractively presented in a setting that depicted the life itself". The result was a new type of introduction to the polar regions. It was based on wide reading and personal experience in both the Arctic and the Antarctic, it gave an enormous amount of information in a few pages, and it was well written. Now, with the added qualification of seven years as director of the Scott Polar Research Institute, Dr. Bertram has brought out a second, and greatly revised, edition of his book.

The history of polar exploration he divides into three stages: the pioneer stage before the First World War, the intermediate stage between the World Wars, and the present modern stage. The progress from stage to stage is "largely to be measured in increasing complexity and enlarged material resources. The simple motive of personal high endeavour . . . has been transformed into national political aspirations".

He begins with a general survey of the polar regions and the animals, birds and fish on which travellers there may exist. Few species occur in the Arctic, and still fewer in the Antarctic, but such as there are congregate in numbers seldom seen in the rest of the man-infested world. Insects and penguins are as numerous as ever, but other species have been all but exterminated at one time or another by man for economic gain, and only survive now through protective legislation. Then the main aspects of polar life are taken in turn and their progress through the three stages, pioneer, transitional and modern, is examined; they are physiology, acclimatization and clothing, dogs, transport, food, organization and leadership. These chapters contain so much that is interesting that extracts are impossible; certainly one would need to be a voracious reader to collect all these facts elsewhere.

Dr. Bertram's long and varied experience of polar affairs makes his appreciation of the "Polar prospect to-day" particularly valuable and interesting to anyone concerned with these regions. The International Geophysical Year of 1957–58 he sees as a turning point in Antarctic history. In spite of the scientific motives that have taken so many nations south there is little doubt but that political changes will result. New sovereign areas, agreed spheres of influence or internationalization, each is possible; all that the author feels certain is that "political factors will largely prevail over the claims of international law as at present understood".

It is a pity that this book has appeared so late in the recent stream of polar books, and may meet with undeserved neglect on this account.

L. M. FORBES

HOW NEUTRONS GET THERE

Neutron Transport Theory

By B. Davison, with the collaboration of J. B. Sykes. (International Series of Monographs on Physics.) Pp. xx+450. (Oxford: Clarendon Press; London: Oxford University Press, 1957.) 75*s*. net.

IN the construction and the performance of nuclear reactors, problems connected with the movements and distribution of neutrons inside the reactors are of prime importance. Some of these problems were solved even before neutrons were discovered, in the setting of astrophysics. The current theory of neutron transport pays due homage to this venerable parentage by much of its terminology and techniques. On the other hand, young as the subject is, it has already outgrown its ancestry by the subtlety and variety of the problems and the demand for the great accuracy in the solutions. Most of the (published) progress of the subject dates from the later years of the Second

World War and onwards; the author of the book under review has a distinguished and well-known record in that progress. He has now produced in a massive and carefully written volume a fine account of the various mathematical methods which have so far been brought to bear on the problems of neutron transport. In his task he received the active co-operation of a number of eminent specialists in the field. Readers who approach this subject with experience in some other branch of physics will be interested, possibly surprised, to read in the book the contributions to transport theory by physicists (for example, Feynman, Fuchs, Pryce) more widely known in other fields.

The book starts with a general statement of the problems involved: this may be equivalently framed either as the Boltzmann equation or as an integral equation. In the greater part of the rest of the book various solutions, analytical and numerical, are considered. The reader is left in no doubt as to which method to apply in a particular situation. The ordering of the treatment is, quite appropriately, to take simpler problems first and consider others in an order of increasing complexity. The result is that roughly the first one-third of the book is 'compulsory reading', after which various sections in the remainder are independent of each other. The intention of the author to make the mathematical treatment detailed and self-contained has been achieved with remarkable feats of economy.

The book is primarily directed to the advanced worker in neutron transport theory. To him the book offers mainly the following three advantages: the opening chapters contain a balanced and precise justification for the physical assumptions of the theory. Secondly, by presenting the subject as a systematic and compact discipline this book promises to be a standard one, as regards form and notation, and as regards the inter-relation of topics treated in the book. Lastly, much of the material is published in this book for the first time.

This book can be strongly recommended to those interested in other branches of transport theory. It is not always that the methods developed in connexion with neutrons can be legitimately applied; nevertheless, there is a great deal to be gained from familiarizing oneself with these methods.

It is a pity that the book makes scarcely any reference to the way in which these elaborate calculations have been tested or put to use. Now it may seem misguided to ask for this kind of information, much of which is probably not at the author's disposal, in what is primarily a text-book of methodology. Nevertheless, one hopes that future circumstances will enable the author to make allowance for a (proverbially deadly) weakness of his reader.

R. Englman

MINERAL REQUIREMENTS OF PLANTS AND ANIMALS

Mineral Nutrition and the Balance of Life

By Dr. Frank A. Gilbert. Pp. xv+350+30 plates. (Norman, Oklahoma: University of Oklahoma Press, 1957.) 5.95 dollars.

Animal and plant physiology have an important link in the mineral nutrition of the plant. Many instances are now known, and others are constantly coming to light, where a deficiency in a food plant has important consequences on animal health. These discoveries have led to greater emphasis on the problems of interrelationships between plant and animal nutrition, and this in turn has intensified investigations on the mineral content of soils of different localities. It is perhaps not surprising that nutritional disorders of animals due to deficiency or excess of minerals were not immediately associated with the mineral composition of the food plant because elements essential to animals are not necessarily essential to plants, and the latter have the facility of accumulating elements which take no part in metabolism but have no harmful effects on their growth. Thus, cobalt is not considered essential for higher plants but the small amount that occurs in plants is of great importance because normally this is the only way in which animals get their essential supplies of this element. Some plants are tolerant to the presence of selenium in the soil, but such plants are toxic to animals.

The story of mineral deficiencies in plants is in itself a fascinating one and Dr. Gilbert has not only given a very complete account of the mineral requirements of plants but also linked it with the question of nutrition and well-being of animals that use these plants as food. The treatment of this subject may be said to be comprehensive since the author considers each element in turn, first from a historical point of view and then how the lack (or in some cases excess) of that element affects plants and animals, including humans. These accounts are linked to the relation between deficiencies and the soils of particular localities with mention of the geographical regions where deficiencies prevail. It is inevitable that most of the latter information refers to the North American continent, where the most intensive work has been done, but available information from other continents is included.

So far about sixty elements have been identified in plants, but only about twenty of these are conceded to be essential either to plant or animal nutrition. The present book, however, deals with thirty-one, including not only the major elements nitrogen, phosphorus, potassium, calcium and magnesium and the trace elements but also others such as aluminium, silicon, selenium, fluorine, arsenic and lead which are of interest by virtue of their toxic properties.

The author has included a chapter on enzymes, hormones and vitamins which seems out of place in a book of this nature. The brief chapter on analytical methods underlines the fact that the book is not primarily addressed to the specialist although there is much in the book which is of interest to those concerned with mineral nutrition and the 1,177 references are a valuable guide to the literature, but by no means exhaustive. The book concludes with a chapter on human nutrition which repeats the main theme of the book that the health of the animal depends on a supply of nutritious forage. The author points out that we are protected by law against harmful drugs but not against inferior food, and pleads for more education and publicity to create a realization of the need for better quality food.

The book is well produced and contains numerous photographs illustrating symptoms of mineral deficiency and toxicity in plants and animals. It can be recommended as a good general account of the mineral requirements of plants and animals.

E. C. Humphries

Selected Combustion Problems, 2

Transport Phenomena; Ignition; Altitude Behaviour and Scaling of Aeroengines. M. W. Thring (Senior Editor). (AGARD Combustion Colloquium, Liège, Belgium, December 5 to 9, 1955.) Pp. viii + 495. (London: Butterworths Scientific Publications; New York: Interscience Publishers, Inc., 1956.) 90*s.*; 12.50 dollars.

THIS is the record of the combustion colloquium, held at Liège in December 1955. Eighteen papers were presented and discussed at some length, the languages used being English and French. Abstracts are rendered in both tongues with occasionally interesting results, and a small subject index of doubtful value is appended.

The papers are, as the main title of the book suggests, on chosen aspects of combustion. The choice naturally has regard to the interests of aeronautical scientists, and the sub-title rather incompletely indicates group headings. The author's aim is generally to survey, and little new experimental work is presented.

There is no doubt that colloquia of this nature are of value in assessing the current state of knowledge and in defining those problems that most clearly call for study. It is good to see evidence that time was allowed for extended discussion.

As to how far the record is of permanent value on the library shelf is another matter. A possible view is that the practical success of the meeting will be measured by the speed with which the papers and discussion become out-dated. Meanwhile, those who are concerned with aero engines (including rocket motors) and their fuels, fundamentally considered, will find ample material for consideration within these pages. J. H. Burgoyne

The Alimentary Tract of the Ruminant

By David Benzie and Dr. A. T. Phillipson. Pp. 24 + 54 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1957.) 27*s.* 6*d.* net.

INVESTIGATION of the gut of the ruminant during the past twenty years has made the chemical changes which go on within the stomach reasonably plain. This is not, however, true of the mechanical activity of the alimentary tract and there is still a considerable degree of doubt as to the way in which food is sorted into that fraction which goes to the rumen and that fraction which is passed along the œsophageal groove to the abomasum, and as to the muscular movements which play a part in the belching which these animals use in order to get rid of the gas produced during ruminal digestion. A relatively new approach to these problems has been made with the use of radiographic studies, a series of which is reported in this volume. Part of the work was done in the Department of Physiology of the Rowett Research Institute, and part in the Department of Anatomy at the University of Manchester. The animals appear to withstand the effect of radiography well and not to be much affected by this experimental method. The book consists largely of an atlas of 54 plates, most of which contain several X-ray photographs of the alimentary tract of young animals (lambs, calves, kids) fed a barium meal. The movements of the gut are obviously complex, but among the interesting points which the series of photographs makes plain is the confirmation of the extra-ruminal contraction described by Weiss as the basis of the belching mechanism. Since the work was carried out predominantly on young animals mainly fed on milk, the part played by the chambers of the stomach other than the abomasum is not made plain, though an interpretation of the activity of the omasum is given. There is every expectation of this most promising method leading to clarification of the muscular movements carried out by each part of the stomach in the alimentary tract of these animals. A. Graham

Structural Psychology

De Humani Mentis Fabrica. By D. and K. Stanley-Jones. Pp. viii + 180. (Bristol: John Wright and Sons, Ltd., 1957.) 21*s.*

THE authors of this book define structural psychology as "a system of psychology erected upon the basic sciences of anatomy and physiology" (page v) and further state that "the contribution which structural psychology has to make to the major problem of philosophy has been to prove that the structure of the mind and the structure of the brain are sufficiently alike in every known point of comparison to warrant the statement that they are identical. By proof of the identity of structure the hypothesis is justified that there is an identity both of location and substance" (p. 160).

It is suggested that emotion originated in palæolithic times when man lived mainly in caves, and these were conditioned to "lust and feeding in the warmth of the night, aggression in the outside cold of the day". Aggression is associated with oral biting and massive discharge of the orthosympathetic system, and in balanced antagonism with oral sucking and the parasympathetic system. Obstruction of the sucking leads to a mass discharge of the orthosympathetic with oral biting.

These basic reactions become associated with the mother, envisaged by the child as the bad mother when it is unsatisfied and the good mother when it is. From her the emotions are transferred to the father and so to society.

It is impossible to describe the whole of the authors' arguments in a few words. They link physiology ingeniously with psychological concepts, but their system is not completely new and is mainly a fresh arrangement of Freudian psychology and organic theories. It should prove interesting to those psychologists interested in physiology and those physiologists psychologically orientated.

The book is clearly printed on non-shiny paper, the style is lucid and should be understood by educated readers even if unfamiliar with the material. There is an excellent index and glossary.

Intermediate Physics
